-severe form of dumping syndrome occurred less
equently in patients with polyposis and cancer
.1%) than in the patients with peptic ulcer (10%)
ter gastrectomy. The frequency of the dumping
ndrome was independent of the use of a short or
ng loop of jejunum for anastomosis; in addition,
e late hypoglycemic syndrome was independent of
e type of gastroenteroanastomosis. Postsurgical
imentary dystrophy, occurring after 3-17 yr.,
s evident in 3 persons. A total of 19 patients
.5%), of whom 6 had repeat surgery (twice in 1
6 patients) for adhesive obstruction, had
rivisceritis. A microcytic anemia of marked
gree was observed in 3 patients. Peptic ulcer
6 yr. after resection was recorded in 5 of 606
.8%) patients. Symptoms characteristic of
ronic gastritis, enterocolitis, cholecystitis
d pancreatitis, were found in 54 of 741 (7.2%) patients 3 yr. after surgery; in some of these, this diagnosis was made before operation. Yearly wt. recording in 100 patients during 5 yr. showed a wt. increase during the first yr. in 73%, no increase in 9% and a decrease in 18%.

8238 INTESTINAL EPITHELIAL ENZYME ABNORMALITIES INDUCED BY 5-FLUOROURACIL: TRANSLOCATION OF NADPH$_2$-DEHYDROGENASE. (E.) Kaufmann, H. J. (Yale U. Sch. Med., New Haven, Conn.), H. M. Spiro and M. H. Floch. Amer. J. Dig. Dis. 12(6): 598-606, 1967.

Graded doses of 5-fluorouracil were given to mice (48) in 2 separate experiments. In the first experiment, 30 mice were divided into 3 groups: 10 received 75 mg/kg 5-fluorouracil i.p. for 5 consecutive days; 10 received 100 mg/kg for 5 days and 10 received no drug. After 5-fluorouracil treatment, 1 animal from each group was sacrificed each day until the tenth day, with the sixth day being the first day after treatment. In the second experiment, 18 mice were divided into 3 groups: 6 were given 25 mg/kg of 5-fluorouracil i.p. for 5 consecutive days; 6 were given 75 mg/kg; and 6 received saline with no drug. Half of the mice in each group were sacrificed at 6 days, and half at 8 days after onset of drug admin. Specimens of midjejunum and descending colon were taken from each mouse for study. In addition, 3 days after completion of therapy, rectal biopsies were performed on 3 patients treated with 5-fluorouracil (dose not specified). Histochemical studies were performed for reduced nicotine-adenine dinucleotide- and reduced nicotine-adenine dinucleotide phosphate dehydrogenase, succinate dehydrogenase, glucose 6-phosphate dehydrogenase, non-specific esterase, and acid and alkaline phosphatases. As small and large intestinal tissue became more severely damaged, enzyme activity was generally decreased. In the colon, but not in the small intestine, reduced nicotine-adenine dinucleotide phosphate dehydrogenase was noted to translocate from a diffuse normal pattern to a luminal border pattern about the crypt and surface epithelial cells. Translocation of this dehydrogenase was most marked in specimens obtained at 8 days with a dose of 25 mg/kg of 5-fluorouracil. The translocation was also observed in 1 of 3 specimens from patients treated with 5-fluorouracil, but in none of 6 normal specimens. Translocation of this dehydrogenase in the colonic crypts and surface epithelium represents the experimental production of "the ulcerative colitis trait" and suggests that this phenomenon is not specific for ulcerative colitis. Reduced nicotine-adenine dinucleotide phosphate dehydrogenase is contained in the mitochondria and its translocation to the luminal border of the epithelial cells in animals treated with 5-fluorouracil implies a reorganization of mitochondria or mitochondrial enzymes secondary to the metabolic derangement induced by the inhibition of DNA synthesis.

8239 THE MASSIVE BOWEL RESECTION SYNDROME. TREATMENT WITH REVERSED INTESTINAL SEGMENTS. (E.) Fink, W. J. (VA Hosp., Fayetteville, Ark.) and J. D. Olson. Arch. Surg. (Chicago) 94(5):700-706, 1967.

The massive bowel resection syndrome frequently occurs when more than 200 cm (7 feet) of small intestine has been resected, and consists of diarrhea, steatorrhea, hypoproteinemia, wt. los and other nutritional disturbances. When such patients are refractory to medical treatment, they are often treated with reversed intestinal segments which slow gastrointestinal emptying time, delay transit time, allow longer food mixing and improve nutrition by increasing abso tion. The literature concerning this procedure is reviewed (8 cases were previously reported using this technic), and 4 additional cases treated in this manner are described. A 49-yr. old Caucasian male had removal of the distal 6 feet of small intestine plus resection of the lower half of the ascending colon for regional enteritis; he experienced the massive small bow resection syndrome and was treated with a 17-cm reversed loop placed between the distal small intestine and upper ascending colon, with excel results. Three other patients, a 23-yr.-old Negro male, a 66-yr.-old Caucasian male and a 65-yr.-old Caucasian female were also treated with varying degrees of reversed intestinal segments; in each case they experienced improve nutrition, reduction in the number of stools pe day and gain in wt. It is suggested that the best location for a reversed loop should be distal to the first 90 cm of jejunum.

8240 THE LYMPHATICS OF THE INTESTINAL MUCO A CLINICAL AND EXPERIMENTAL STUDY. (E.) Bank, S. (Groote Schuur Hosp., Cape Town, S. Africa), G. Fisher, I. N. Marks and A. Groll Amer. J. Dig. Dis. 12(6):619-632, 1967.

During a 3-yr. period 309 peroral jejunal biops specimens were obtained from 290 subjects. Control subjects included 77 patients in whom various diseases (53 with irritable colon, 10 with gastroduodenal ulceration, 4 each with cholelithiasis and bronchiectasis, 5 with dermatitis and 1 with Ladd's syndrome) did not have any bearing on the state of intestinal lymphatics. The patient group included 232 wit various other diseases (109 specimens from patients with small intestinal disease; 34 from those with pancreatic disease; 32, gastric surg 8, ulcerative colitis; 6, hepatic cirrhosis; 4, gross gastric hypersecretion; 4, gastrointestin tract carcinoma; 14, pernicious or iron-deficie anemia; 14, congestive cardiac failure; 4, an established collagen disease and 3 with a nephrotic syndrome). The biopsy specimens were reviewed with regard to the frequency with whic mucosal lymphatic channels were visualized on routine microscopy, and an attempt was made to measure their approx. size. Distinct lymphatic channels were seen in 1 or more villi in 114 of 309 specimens at magnifications of 100 times an 40 times. In order to be certain of abnormal mucosal lymphatic dilatation, it was thought th the lymphatics should be greater than normal size and should be present in several villi.

3 patients exceeded the normal range; the
natic block appeared to be at a lymph-gland
in 2 and at a level of the muscle layer
ne intestine in 1. It is suggested that
tron microscopy and multiple biopsy specimens
necessary to be certain of lesser degrees of
natic dilatation, especially those less than
in diameter. Attempts to produce lymphangi-
sia experimentally in the dog (i.e., to
ent the size or the number of mucosal lympha-
, with forced fat feeding, high or low thoracic
ligation, or regional lymphatic blockage for
ods up to 6 mo.) were successful. The
ible reasons for the occurrence of protein-
ng enteropathy without lymphangiectasia
presented, and the difficulties in differ-
ating lymphatics from empty blood vessels
villous edema are discussed.

AN ULTRASTRUCTURAL STUDY OF THE SMALL INTESTINE AFTER TOTAL VAGOTOMY. (E.)
ott, R. L. (U. Mississippi Med. Ctr.,
son), W. O. Barnett and M. C. Elliott. Surg.
c. Obstet. 124(5):1037-1042, 1967.

sy specimens of the jejunal mucosa were ob-
ned before vagal denervation and at intervals
, 2, 4, and 6 wk. as well as at 3, 4, 6 and
no. after vagotomy in 12 adult mongrel dogs;
pleteness of vagotomy was determined by the
ervation of a specimen taken from the interposed
of ileum between the stomach and duodenum.
sue was prepared for electron microscopy and
edded in Epon-812. Sections, 1 μ thick, were
mined with the phase microscope to determine
site to be examined further by electron
roscopy, and ultrathin sections were examined
the latter method. The villi of the jejunal
osa maintained their anatomic integrity
oughout the period of study. Comparative
dies (electron microscope) failed to reveal
changes in ultrastructural components of the
unal mucosa after vagotomy. Microvilli,
ochondria, endoplasmic reticulum, Golgi appara-
and the terminal web area all remained
mal. It is concluded that ultrastructural
ponents of the jejunal mucosa maintained their
mal morphologic integrity for a period of
m 1 wk.-1 yr. after vagotomy.

2 GASTRIC EVACUATION AND PROPULSIVE INTESTINAL MOTILITY FOLLOWING RESECTION
THE SMALL INTESTINE IN THE RAT. (E.) Nylander,
(Acad. Hosp., Uppsala, Sweden). Acta Chir.
nd. 133(2):131-138, 1967.

a series of 211 rats, divided into a high
ection group of 60 rats, a low resection group
60, and a control group of 91, propulsive in-
stinal motility was studied following resection
the proximal jejunum, and of the distal ileum.
was inferred that the altered propulsive motil-
y in the resection groups (demonstrated by the
stribution of the radioactive test dose in the
omach and intestine at the given experimental
junctures) is due to dynamic factors, not to a mechanical one. Also, displacement of a radioactive dose towards the site of the intestinal resection, i.e., proximally when a proximal, and distally when a distal, segment of the small intestine is removed, led to the assumption that a differentiated propulsive function may exist in the small intestine, the autonomy of which belongs to each consecutive part of the intestinal tract. The eliminated function is anatomically related to the resected portion. Further experiments are suggested to elucidate this hypothesis.

8243 RESECTION OF THE SMALL INTESTINE IN RATS. III. MORPHOLOGICAL CHANGES IN THE INTESTINAL TRACT. (E.) Nygaard, K. (State Hosp., Oslo). Acta Chir. Scand. 133(3):233-248, 1967.

Morphological studies of the alimentary canal of 117 female rats were carried out following resection of various lengths and different parts of the small intestine. The types of operations performed (and in parentheses the number of rats) were: sham (14); jejunal (8) and ileal (8) transections; resections of the proximal 25% (10), third 25% (7), middle 50% (7), proximal 75% (31) and distal 75% (21); bypass proximal 75% end-to-side anastomosis (7); bypass middle 50% side-to-side anastomosis (4). The results indicate that various processes contribute to the structural changes in the alimentary tract after the resections; these processes were: atrophy; 2 kinds of hypertrophy (local and diffuse) involving all layers of the intestinal wall. Postoperative resemblance between the pattern of epithelial surface regeneration and the adaptation of absorption was evident. The colon increased in wt., length and circumference after large distal resections of the small intestine. Bypassing caused anatomical changes similar to those seen after resection. Intraoperative measurement of the small intestine, and preservation of its anatomy when it is removed and measured postoperatively, was emphasized.

8244 SEGMENTAL INFARCTS OF THE SMALL INTESTINE AND MESENTERIC ADENITIS IN THAI CHILDREN. (E.) Headington, J. T. (Chiengmai U. Sch. Med., Thailand), S. Sathornsumathi, S. Simark and W. Sujatanond. Lancet 1(7494): 802-806, 1967.

Clinical, laboratory, radiologic and pathologic findings are described in 5 Northern Thai children (4 boys, 1 girl; aged 4-7 yr.) with gangrenous segmental infarcts of the small intestine associated with mesenteric adenitis and marked reactive hyperplasia of the mesenteric lymph nodes. Two of 5 died of irreversible shock and paralytic ileus, before surgical intervention could be undertaken. Characteristic presenting symptoms included vomiting and acute, febrile diarrhea, characterized by brownish, watery stools without gross blood or mucus but strongly positive for occult blood. Paralytic ileus developed within 48-72 hr. after the onset of symptoms, accompanied by serous ascites and followed by severe shock which quickly became irreversible. X-ray at this time showed dilatation and gas-filled loops of small intestine, accompanied by significant thickening of the wall of the involved segments, reduction of the caliber of their lumens and the appearance of fixation. The condition is said to occur in young children, most frequently in boys, and note is made that all of the patients reported were hospitalized at, or shortly after, the end of the rainy season. Initial treatment was symptomatic, including replacement of electrolytes, and was followed, in 3 of 5 who lived to laparotomy, by resection of the affected segment or segments of small intestine.

8245 PROGRESSIVE VILLOUS ATROPHY OF THE ILEUM USED AS A URINARY CONDUIT. (E.) Goldstein, M. J. (Mem. Hosp. Cancer Allied Dis., New York, N. Y.), M. R. Melamed, H. Grabstald and P. Sherlock. Gastroenterology 52(5):859-864, 1967.

Patients (15 men, 7 women, 36-82 yr.) with pathological diagnosis, prior to cystectomy and ileal conduit construction, of epidermoid or transitional cell carcinoma of the bladder (20), "bladder tumor" (1), papillomatosis of entire bladder (1) were studied. Twenty received irradiation of the bladder (tumor doses, 3000-6000 r) prior to conduit construction; interval between construction and biopsy was 7 days-5.5 yr. Suction biopsies of ileal bladder (24) were obtained from all 22; specimens of normal ileum were obtained from 2 during conduit construction. Biopsies were obtained with the Woods tube; the capsule was inserted approx. 5 cm beyond the mucocutaneous margin of the stoma. Specimens were immediately removed from the capsule, oriented on heavy blotting paper, fixed in 10% neutral formalin, serially sectioned, stained with hematoxylin, eosin, mucicarmine, periodic acid-Schiff and observed by 1 person without knowledge of conduit-biopsy interval. Progressive villous atrophy was observed, beginning as early as 1 wk., with considerable individual variation in rate and degree. The changes ranged from mild-to-moderate villous, mucosal and submucosal edema with consequent broadening, blunting and apparent shortening of villi within the first few mo. The change was patchy or irregular and interspersed with areas of relatively normal or mildly edematous villi. For the next few mo. there was progressive shortening of the villi with partial replacement by deeper crypt formation. Blunting and broadening of villi progressed to loss of villous structure and flattening of mucosa. The rate of loss of villous structure varied among individuals but was usually complete by 2 yr. No consistent change was observed in the number of goblet cells or Paneth cells. Mild inflammatory infiltrate in the lamina propria was found in a few cases, and was not correlated with operation-biopsy interval.

8246 CORRELATION OF JEJUNAL FUNCTION AND MORPHOLOGY IN PATIENTS WITH ACUTE AN CHRONIC DIARRHEA IN EAST PAKISTAN. (E.) Kent, T. H. (Walter Reed Army Inst. Res., Washington, D. C.) and J. Lindenbaum. Gastroenterology 52(6):972-984, 1967.

A total of 225 jejunal mucosal biopsy specimens were obtained from 81 subjects in East Pakista these included 7 normal Pakistanis, 16 America in Pakistan (14 of whom were Peace Corps volunteers), 12 subjects with cholera, 30 with acute diarrhea other than cholera (2 with noncholera vibrio infection, 2 with nonvibrio cholera, 2 with typhoid fever, 2 with shigellosis, 1 with dysentery of unknown cause, 1 with staphylococ food poisoning, and 20 with acute selflimited diarrheal illnesses unassociated with recognize pathogens on stool culture), 13 patients with chronic diarrhea with malabsorption (2 of whom had undergone gastrectomy, 1 had amebiasis and 1 had chronic liver disease), and 3 with chroni diarrhea without malabsorption. Ten of 81 were treated for 2-14 wk. with p.o. tetracycline (1 or 2 g daily). Biopsies were graded accordi to severity of morphological alteration under t dissecting microscope and on histological secti Jejunal lesions were similar in character in patients with acute diarrheal illnesses, chroni malabsorption syndromes and in normal controls, but there were differences in severity of damag Jejunitis was most severe during or shortly aft an acute diarrheal episode or in those patients with chronic malabsorption of unknown cause (tropical sprue). Severity of the lesions decreased after recovery from acute diarrhea and some patients with chronic malabsorption treate with tetracycline. The extent of mucosal damag correlated moderately well with xylose absorpti less well with fat absorption and least well with vitamin B_{12} absorption. Absorptive functi correlated better with the histological appeara of the jejunal mucosa than with the architectur patterns seen under the dissecting microscope.

8247 CARCINOID-ISLET CELL TUMORS OF THE DUODENUM. (E.) Weichert, R. (Tulane U. Sch. Med., New Orleans, La.), R. Reed and O. Creech, Jr. Ann. Surg. 165(5):660-669, 1967.

Sixteen cases (8 males, 8 females) of carcinoid islet cell tumors of the duodenum are described there were 10 patients with ulcer and 6 without ulcer. Of 6 without duodenal ulcer, 3 were asymptomatic and the tumors were found at autop the other 3 patients had vague abdominal compla or epigastric cramping pain suggestive of intermittent duodenal obstruction. In 10 patients with ulcerogenic tumors, symptoms varied from those of uncomplicated duodenal ulcer to those suggestive of Zollinger-Ellison syndrome. Duration of symptoms ranged from a few days to 15 y Vomiting was severe in 3 patients and was accompanied by severe diarrhea in 1; each of these later proved to have the Zollinger-Ellison syndrome. Radiologic examination of the upper

intestinal tract and gastric analysis were
st helpful aids in diagnosis. The gastro-
inal series showed abnormalities in 12 of
ients examined. Gastric analyses were done
f 10 patients with ulcers; 5 with hyper-
ion were classified as having the Zollinger-
n syndrome. Thirteen patients with duodenal
were operated on; in 10, surgery was done
mptoms of ulcer and in 3 for removal of
s seen on radiology. All those without
ecretion remained well after operation.
6 with Zollinger-Ellison syndrome obtained
ete relief of symptoms after removal of a
tumor and part of the stomach. Of 3 with
ant tumors who required total gastrectomy,
survived. A sixth patient remained
matic after 2 partial gastrectomies.
arity in microscopic appearance did not allow
nction of carcinoid from islet cell tumors.
proposed that carcinoid and islet cell
s share a common origin in the argentaffin
based upon the following reasoning.
logically, the tumors are indistinguishable.
rgentaffin cell, thought to be the parent
of carcinoid tumors, can be traced embryo-
ally to the islets of Langerhans. Function-
arcinoid and islet cell tumors have been
in the stomach, duodenum, pancreas, liver
ronchi; and argentaffin cells are present
ese derivatives of the foregut. Pancreatic
cell tumors and metastatic tumors resembling
noid and islet cell tumors produce insulin.
eatic and duodenal islet cell tumors produce
in and the Zollinger-Ellison syndrome.
eatic ductal, acinar, and islet cell tumors
ce serotonin and the carcinoid syndrome.
rine of one patient with an ulcerogenic tumor
e duodenum contained 5-hydroxyindole acetic
Carcinoids of the foregut are associated
increased incidence of gastrointestinal
rs.

EFFECTS OF GASTRIC SURGERY UPON GASTRIC EMPTYING IN CASES OF PEPTIC ULCERATION. Buckler, K. G. (Royal Infirm., Bristol, and). Gut 8(2):137-147, 1967.

ric emptying times in excess of 6 hr. were in only 16 of 130 normal subjects under 60 of age (including 4 of 32 who were under in 4 of 10 aged 61-70 and in 1 of 10 aged r over. Emptying times of 2 hr. or less seen in only 3 of 130, 2 of 10 and 0 of 10, . Emptying times of less than 2 hr., 2-4 hr., hr., 6-8 hr. and more than 8 hr. were lated for 12 patients with hiatal hernia, as ows: 2, 3, 4, 2 and 1, resp. (with prolonga- only in the presence of associated ulcer); 24 with pernicious anemia, they were 12, 9, and 0, resp. (with increased speed ciated with achlorhydria); for 193 with enal ulcer, they were 4, 59, 72, 41 and 17, . (with prolongation associated with very ed hypersecretion); for 83 with benign ric ulcer, they were 3, 19, 31, 24 and 6, . (with prolongation only in the presence of ss scarring of the lesser curvature); for 14 gastric carcinoma, they were 0, 2, 2, 1 and resp. Comparable tabulations for gastrectomized ients with a Polya anastomosis (45 cases) e 11, 26, 7, 1 and 0, resp.; with a Billroth nastomosis (41), they were 2, 18, 17, 4 and 0, p. Following pyloroplasty or pylorectomy (8), y were 1, 0, 3, 3 and 1, resp.; following troenterostomy (9), they were 0, 4, 4, 1 and resp.; following vagotomy alone (15), they e 0, 0, 0, 6 and 9, resp. When additional otomized patients were grouped in terms of ociated surgical technics, they were as lows: Polya (22) = 2, 6, 4, 4 and 6, resp.; lroth I (27) = 0, 4, 3, 5 and 15, resp.; oroplasty (35) = 0, 0, 4, 11 and 20, resp.; troenterostomy (37) = 0, 3, 8, 22 and 4, resp. is concluded that there is no evidence that tric stasis is associated with either gastric duodenal ulceration, although it may company gastric cancer; that gastric emptying speeded after gastric resection or bypassing e duodenal circuit; that vagotomy, with or thout drainage, delays gastric emptying gnificantly.

8 ROLE OF CALCIUM IN GASTRIC HYPER- SECRETION, PARATHYROID ADENOMA AND PTIC ULCER. (E.) Barreras, R. F. (U. sconsin Med. Sch., Madison) and R. M. naldson, Jr. New Eng. J. Med. 276(20): 22-1124, 1967.

a 37-yr.-old woman with 3 parathyroid enomas, duodenal ulcer, hypercalcemia and rked gastric hypersecretion, parathyroidectomy d to restoration of normal serum Ca levels, companied by a reduction of gastric secretion normal levels. Ca admin. was terminated 6 . after surgery. Subsequent induction of hypercalcemia on several occasions was always associated with a rise of gastric secretion to the preoperative levels. Preoperative serum Ca was 12.6 mg/100 ml and the basal acid output was 19.1-20.1 mEq/hr. During the first postoperative yr., these values were reduced to 9.6 mg/100 ml and 2.1 mEq/hr., resp. Preoperative peak acid output had been 57.6 mEq/hr. Response to betazole hydrochloride declined to 45.6 mEq/hr. 1 wk. postoperatively; then decreased progressively to 24.5 mEq/hr. 1 yr. later. It is suggested that a gastric secretory response to calcemia may account for peptic ulcer in some hyperparathyroid patients.

8279 PARIETAL-CELL ANTIBODIES IN PATIENTS WITH DUODENAL ULCER AND GASTRIC CANCER. (E.) Kravetz, R. E. (Yale U. Sch. Med., New Haven, Conn.), S. Van Noorden and H. M. Spiro. Lancet 1(7484):235-237, 1967.

The presence of parietal cell antibodies was sought in 398 patients with duodenal or gastric ulcer. The patients were classified into 6 groups containing 131, 42, 79, 17, 50, and 67 patients. Of the 131 control patients without gastrointestinal, diabetes or thyroid history, no correlation between age and the presence of antibodies was found (13% of the 131 without diabetes, and 42% with it had circulating parietal cell antibodies). Of the 42 (with pernicious anemia), antibodies occurred in 83%, with no correlation between duration of disease and antibodies. Of the 17 (with gastric ulcer), 17% had antibodies. Of the 50 (with history of subtotal gastrectomy), 40 had duodenal ulcer and 8 had gastric ulcer with 1 case among the 40 with parietal cell antibodies. Of the 67 (with gastric carcinoma), 9% had parietal cell antibodies. The Coons and Kaplan gastric antibody technic, gastric mucosal biopsy, and enzyme histochemistry were the technics employed for the study. It is concluded that parietal cell antibodies are most often found in patients with pernicious anemia. Duodenal ulcer patients as a group are less likely to show these antibodies after subtotal gastrectomy, when gastritis is expected. The incidence of parietal cell antibodies is low in patients with gastritis of gastric carcinoma. It appeared that parietal cell antibodies and gastritis may be independent characteristics, related in some individuals; parietal cell antibodies may form as a result of gastritis only in patients genetically inclined.

8280 LIBIDO CHANGES IN DUODENAL ULCER PATIENTS. (Ser.) Josimović, I. (Gen. Hosp., Bijeljina, Yugoslavia). Srpski Arh. Celok. Lek. 94(6):587-596, 1966.

A study was made on 100 duodenal ulcer patients who were medically treated (with drugs) and 20 who underwent gastric resection; all were males, 21-50 yr. old. All other sources for changes of libido were excluded. After the onset of disease, 49 of 100 patients treated medically exhibited changes in libido; in 30% it was decreased (1 coitus every 15-30 days), in 10% it was very diminished (1 coitus every 5 wk.-4 mo.), 3% were impotent, but in 6% the libido increased (2-3 coituses/day). After gastrectomy, 14 of 20 subjects had a decreased frequency of coitus, which had decreased before surgery in 11 of 14, and continued to decrease further after surgery. Four subjects were unable to work; the remaining 6 subjects had a normal libido before and after surgery, and their working ability was unimpaired. The duration of ulcer disease, age and nutritional condition of the patients had no essential influence on the changes of libido. Patients who lived and worked in cities had markedly greater changes in libido than did those from a rural, agricultural population. Libido changes were more pronounced in neurotic individuals than in emotionally stable patients. A normal libido was found among 33.3-50% of the office workers and qualified and unqualified manual laborers, and among 60% of the farmers; a normal libido was found among 26.8% of the neurotic individuals and among 64.8% of those considered stable. Among the latter farming was the principal occupation, and office workers were found least frequently in this group. The situation was reversed among those considered to be neurotic. In addition to endocrine dysfunction, changes in libido among duodenal ulcer patients are most likely to be explained by a neurotic inhibition of the normal expression of sexuality. The condition of the libido may serve as a guide for the ability of patients to tolerate surgery, i.e, if a patient had a normal libido before surgery, the latter will probably be well tolerated; however, if a patient's libido was diminished prior to surgery, it will continue to decrease after surgery; the latter will be poorly tolerated, and invalidism may possibly develop due to inability to work.

8281 GASTRIC MUCOSAL COATING AND GASTRIC EMPTYING TIME OF ANTACIDS. A GASTROCAMERA STUDY. (E.) Morrissey, J. F. (U. Wisconsin Sch. Med., Madison), T. Honda, Y. Tanaka and G. Perna. Arch. Intern. Med. (Chicago) 119(5):510-517, 1967.

The rate of emptying and the mucosal coating properties of 4 antacids (nonreactive aluminim hydroxide and magnesium trisilicate, magnesium-aluminum hydroxide, magnesium-aluminum hydroxide and simethicone, and $CaCO_3$ powder) were studied in normal volunteers (21-45 yr. old) and in patients with gastric ulcers by the technic of intragastric photography using the GT-5 gastrocamera. The antacids distributed themselves within the stomach largely by gravity with only slight adherence to the mucosal surface. The majority of subjects had only minimal amounts of antacid present 1 hr. after admin., most of which coated the distal posterior wall of the antrum. There were no differences between normal volunteers and patients with gastric ulcers and no differences between the antacids tested. Gastric ulcers tended to mechanically trap antacid but otherwise showed little, if any, specific affinity for the antacid tested. Smal doses of antacid (8-10 ml) were emptied more rapidly than larger doses (30 ml) by most, but not all, subjects. Duration of the presence o antacid was greatly prolonged by the prior admin. of atropine. Bubbling within the stomac sufficient to affect antacid distribution was never observed. The results of this study support the recommendation that fasting peptic ulcer patients should receive a dose of an antacid every hr. It is possible that the frequency of antacid admin. can be reduced by the concomitant admin. of an anticholinergic drug.

8282 IN SITU pH OF DUODENAL BULB CONTENTS I NORMAL AND DUODENAL ULCER SUBJECTS. (E.) Archambault, A. P. (Mayo Clinic, Rocheste Minn.), R. A. Rovelstad and H. C. Carlson. Gastroenterology 52(6):940-947, 1967.

The pH of duodenal bulb contents was recorded with a guarded, in situ, glass electrode in 75 subjects, 16 of whom had duodenal ulcer; none of the patients had received anticholinergic drugs for at least 2 wk. before being studied. The antrocutaneous and duodenocutaneous potenti differences were simultaneously recorded from flowing KCl bridges attached to the glass electrode lead, and potential difference patterns were used to position the glass electrode and to monitor its location. Simultaneous cinefluorography confirmed that a potential difference between duodenum and gastric antrum of greater than 15 mvolt (with duodenum more positive) was a reliable sign tha the glass electrode was in the duodenal bulb. In both normal and ulcer subjects the mean duodenal bulb pH was significantly greater than antral pH. In ulcer patients, the mean duodena bulb pH (2.9) was significantly lower than norm (4.5). Both normal and ulcer antral pH values were similar (1.7). There was no significant difference between ulcer and control groups wit respect to the pH of antral or postbulbar duodenal contents. Duodenal bulbar pH was much less stable than antral pH. Postbulbar duodena pH was higher and more stable than the pH of th duodenal bulb.

8283 TREATMENT OF PEPTIC ULCER WITH LOW-POTASSIUM DIET. (Pol.) Bojanowicz, K (Inst. Intern. Dis., Acad. Med., Lodz, Poland). Pol. Tyg. Lek. 21(45):1721-1726, 1966.

The author reviews his own work and the pertine literature concerning the experimental basis of the so-called low-K diet in the treatment of peptic ulcers. This is followed by a discussio of the composition of the low-K diet, its effec my, method of admin., comparison with other ne diets, the results of treatment and the diet in gastric or duodenal hemorrhage. therapy of active peptic ulcer should follow ollowing sequence: the initial diet: 110 g ins, 125 g fats, 430 g carbohydrate and of K for a total of 3380 calories; 2) trans- al diet A: 110 g proteins, 120 g fats, carbohydrates and 2.8 g K for a total of calories; 3) transitional diet B, 105 g pro- , 105 g fats, 330 g carbohydrates and 3 g of a total of 2685 calories and, finally, 4) ermanent diet, consisting of 105 g proteins, fats, 320 g carbohydrates and 3 g K for a of 2600 calories. Such a dietary regimen us low in K and rich in calories, proteins, and carbohydrates, as well as containing ins A, B, C and D, Ca, P, Fe, cholesterol Cl. The meals are frequent but small in vol. regimen is suitable to the dynamics of peptic disease and is better tolerated and yields er results than other routine methods, as nstrated by results of the author's long-term ies on more than 600 patients treated under ical or outpatient conditions.

SIDE EFFECTS OF CARBENOXOLONE SODIUM: A STUDY OF AMBULANT THERAPY OF GASTRIC

R. (E.) Montgomery, R. D. (East Birmingham ., England). Gut 8(2):148-150, 1967.

enoxolone sodium was admin. to 50 outpatients gastric ulcer (50 mg 3 times a day for 6 If the ulcers failed to heal, the dose was ated for another 6 wk. Sixty percent of all ents were symptom-free in 12 wk. Side cts were observed in only 3 of the fifty ents. These patients, who were over 60 and were hypertensives, exhibited ankle edema, taxis, and a rise of diastolic pressure of m Hg or more. One of the 3 patients loped congestive heart failure and died 10 after discontinuing the drug. In the ining 47 patients, the trend for the blood sure was upward; the mean change in the e series was + 7 mm systolic and + 4 mm tolic; the mean serum K level in 32 cases at end of treatment was 4.1 mEq/liter, and the fall in 18 subjects was 0.3 mEq/liter. No ious loss of K was found. It is concluded t Carbenoxolone sodium in the dosage of mg/day is a safe drug in patients in the ence of hypertension, chronic cardiac, renal hepatic disease, and it should not be given conjunction with steroid therapy. The short- m effect on the ulcer niche of this drug ms to be encouraging, although the therapeutic ue in this dosage has yet to be proved.

5 DIFFERENT SURGICAL THERAPIES IN IDENTICAL TWINS WITH DUODENAL ULCERS.

) Lawton, R. L. (U. Iowa, Iowa City), E. S. ntnall and R. M. Freeman. Gastroenterology 4):709-712, 1967.

h twins presented with a perforated duodenal er 1 yr. apart; metabolic studies were carried out simultaneously on both, well after operation. In the first (1; duodenal ulcer with a partial pyloric obstruction), a Hofmeister type partial gastrectomy (distal 2/3 resected) with a retrocolic gastrojejunostomy was performed; an incidental operative finding was cholelithiasis with an uninflamed gallbladder, which was removed; he received 1500 ml transfused blood during the operation. In the second (2), a perforated (sealed-off) duodenal ulcer was found and closed; 1 mo. later a transabdominal vagotomy and pyloroplasty (Heineke-Mikulicz type) was performed; an incidental operative finding was cholelithiasis with an uninflamed gallbladder; the gallbladder was removed; no blood was given. The first died of coronary thrombosis after 5 yr.; (2) is alive after 10 yr. They were studied in a metabolic ward on 4 occasions over 2 yr. Daily fecal fat excretion of (1) was twice that of (2) during the first 3 periods; during the fourth, fecal fat excretion of (2) was less than 10% of intake, while (1) excreted 24% of ingested fat. Fecal fat excretion of (2) was at the upper limits of normal; that in (1) was grossly abnormal on all 3 occasions. Both were in positive nitrogen balance on each occasion, and differences were less striking. This may have been secondary to poor dietary intake prior to hospitalization. Both showed substantial wt. gain. The results confirm the hypothesis that gastrectomy, when compared with vagotomy, is associated with a significant increased fecal fat loss.

8286 RECURRENT UPPER GASTROINTESTINAL HEMORRHAGE IN PEPTIC ULCER. (E.)

Borland, J. L., Sr. (1661 Riverside Ave., Jacksonville, Fla.), W. R. Hancock and J. L. Borland, Jr. Gastroenterology 52(4):631-637, 1967.

In a 10-yr. study of gastrointestinal hemorrhage, all those with hiatal hernia, esophageal or gastric varices, cirrhosis, malignant diseases, telangiectasia, and blood dyscrasia were excluded; only those with hematemesis or tarry stools on admission, symptoms of peptic ulcer, and/or X-ray or pathological evidence of ulcer were included. Of 456 patients, 283 were followed for 1 yr. or longer; 257 for 2; 131 for 5; 25 for 10. Of 173 followed for less than 1 yr., 23 died with the initial hemorrhage; 150 were lost to follow-up. Overall mortality was 5% (23 of 56). Among 105 patients experiencing 173 recurrent episodes of bleeding, only 2 deaths occurred (1.9%). There was a gradual increase in mortality with increasing age at initial hemorrhage; the percentage of patients under 50 yr. dying of initial hemorrhage was not significantly different from that of those 50-79 yr.; the difference was significant when those over 80 yr. were included. Those who required 3 U of blood or less in the initial hemorrhage had a 2.7% mortality; 4-6 U, 4%; 7-9, 16.1%; 10 or more, 26%. There was a significant difference between those requiring less than 6 U blood and those requiring more. Age did not significantly affect the chance of having 1 or more recurrences for patients followed for 3, 5, and 7 yr.; the overall chance of recurrence depended partly on the length of follow-up. Age at initial hemorrhage had no substantial effect on the severity of the first recurrence. Severity of recurrent hemorrhage did not depend on severity of initial hemorrhage. There was no substantial effect on the severity of recurrent hemorrhage relative to the number of transfusions required at the initial hemorrhage.

8287 AN EVALUATION AND COMPARISON OF THE EARLY AND LATE RESULTS OF STANDARDIZED POLYA GASTRECTOMY.

(E.) Kemp, D. (West Middlesex Hosp., Isleworth, England). Gut 8(2): 151-165, 1967.

A comparison of results of 370 Polya-type gastrectomies divided in 2 groups was made; the early group (1950-1951) included 120 cases, the later group (1959-1963) 250 cases. The overall operative mortality was less than 0.3%. The male:female ratio was 3.9:1, but above the age of 40 yr. the ratio decreased in both groups. The ulcer pathology was constant in both groups; gastric ulcers accounted for 30% and duodenal ulcers for 70%. Gastric ulcers were more pronounced in the females of both groups. There was a high incidence of nausea, fullness and dumping in the 1950-1951 group females; for the early and late groups the dumping syndrome incidence was 5.8% and 5.5%, resp., while, 32% and 21%, resp., experienced postoperative nausea, fullness, vomiting, diarrhea, recurrent ulceration and bleeding. The recurrent ulcer rate was 1.3%; there were 5 cases of melena and hematemesis, of which 3 patients gave a history of aspirin ingestion. Wt. loss in each group was approx. 10%, the majority of the patients gaining or maintaining their own wt. There was a high incidence of anemia in all categories except for the 1959-1963 males; 36% of males over 45 and 20% of males under 45 were anemic in the 1950-1951 group. Of premenopausal females in the 1959-1963 group, 50% were anemic, while there was 69% of females over 45 that proved to be anemic. The incidence of vitamin B_{12} deficiency was 14% at 16 yr. after gastrectomy, but only 3 cases had values below 140 pg/ml. Duodenal ulcer patients had a mean value of 349 pg/ml and gastric ulcer patients had 255 pg/ml compared with the mean for normal subjects of 472 pg/ml.

8288 ANASTOMOTIC ULCERS.

(E.) Andros, G. (Massachusetts Gen. Hosp., Boston), G. A. Donaldson, S. E. Hedberg and C. E. Welch. Ann. Surg. 165(6):955-966, 1967.

Over a 50-yr. period at the Massachusetts General Hospital, 326 cases of clinically diagnosed anastomotic ulcer were found; 263 (81%) were in men and 63 (19%) in women. The ulcers were located in the duodenum in approx. 98% of the cases, and in the stomach in 2%. Review o the type of operation performed before development of anastomotic ulcer showed that 178 (55% had posterior gastroenterostomy alone, and 124 (40%) had gastric resection. A total of 87 (2 were treated medically, but operations for marginal ulcers were performed on 239 (73%) of the patients; of these, 23 required a second operation for second anastomotic ulcers. In t entire series, there were 16 deaths; but in th period 1947-1966, operative mortality was only 3%. Follow-up studies of 5 or more yr. durati were carried out on 145 patients. Excellent o good results were found in 104 (72%) of 145 patients after 5 yr.; 11 (7%) had fair results and poor results were found in 30 (21%); of th latter, poor results were due to recurrent ulcers in 26, hemorrhage in 3 and severe malnutrition in 1. Of the 26 with recurrent ulcer, 17 had a second operation and 1 had 2 operations to relieve the ulcer; 13 (9%) of th total were converted to excellent results by this secondary operation in the follow-up peri of 5 yr. or more after the second operation. No specific operation was immune to poor resul When the primary operation was a posterior gastroenterostomy, an adequate gastric resecti plus vagotomy gave the best results. If the previous operation was an inadequate gastric resection, a higher gastrectomy plus excision retained antral tissue was necessary in additi to vagotomy. In this series, 2% of the patien eventually required total gastrectomy for control of the ulcer. Finally, it is suggested that increased use of the gastroscope will lea to a more accurate differentiation of gastriti and gastric or stomal ulcer and facilitate a better diagnosis.

8289 FIFTY PER CENT GASTRECTOMY OR PYLOROPLASTY, WITH VAGOTOMY, FOR DUODENAL ULCER. I. EFFECT UPON HOLLANDER TEST RESULTS

(E.) Brochu, F. L. (VA Hosp., Dallas, Tex.), J. L. Doerr, G. K. Hempel, D. M. Dennis, J. L. Gough and R. P. Hays. Amer. Surg. 33(6): 467-474, 1967.

Of 57 patients with duodenal ulcer treated by vagotomy, 28 had pyloroplasty, and 29 had a 50 gastrectomy on an oblique line removing two-thirds of the lesser curvature, with gastrojejunostomy. Hollander tests were admin. afte a 12-hr. collection of fasting gastric juice. Of those with a rise in free acidity, 20 had received pyloroplasty and 7 a 50% gastrectomy; a rise in total, but not free, acidity, was found in 2 pyloroplasty patients and in 12 wit a 50% gastrectomy. No rise in acidity was four in 6 with pyloroplasty and in 10 with a 50% gastrectomy. A rise in total acidity, free or combined, was found in 22 pyloroplasty patient and in 19 gastrectomy patients. In no case di the result change between a 6-mo. and 12-18 mo. test. It is shown that the choice of drainage

edure after vagotomy affects the incidence
ositive", or free acidity, responses to the
ander test. The response of total, rather
free, acidity may provide a better index of
nplete vagotomy after insulin-induced hypo-
emia. The incidence of incomplete vagotomy
increased 3-fold, when this interpretation
applied to results of tests in patients
r vagotomy and gastrectomy-gastrojejunostomy.
he free acidity response is of prognostic
ificance, 50% gastrectomy and gastro-
nostomy may remove 2 out of every 3 patients
have incomplete vagotomy, from that group
ect to recurrence of ulceration. It is
ght that the mechanism of protection is the
wance of regurgitant-buffering by duodenal
es, with the danger of antral stimulation
ved.

OBSTRUCTING PEPTIC ULCERS. RESULTS OF
TREATMENT. (E.) Fisher, R. D., P. A.
t and G. D. Zuidema (Johns Hopkins Hosp.,
imore, Md.). Arch. Surg. (Chicago) 94(5):
727, 1967.

tal of 65 patients with obstructing
roduodenal ulcers was operated on between
-1965 at the Johns Hopkins Hospital; sub-
l gastrectomy and Billroth II anastomoses
used in 75% of the cases. Postoperative
ogastric decompression was used in all
ients; tube gastrostomy was not used. The av.
ation of postoperative gastrointestinal
ompression was 40 hr., with a span of 24-108
The av. duration of gastrointestinal
ompression after surgery was approx. the same
gastroenterostomy, gastric resection, or
oroplasty. There were no significant differ-
es in the duration of postoperative gastro-
estinal decompression required after vagectomy
association with any of these procedures.
toperative hospital convalescence av. 9.4
s, ranging from 6-35 days for the entire group;
atients required postoperative hospitalization
ger than 14 days. Nasogastric suction was
nd to be an effective method of gastro-
estinal decompression; the relatively short
iod of nasogastric suction used in this entire
up of patients with gastrointestinal
truction indicates that prolonged gastro-
estinal decompression is not necessary. In
ition, the completely uncomplicated convales-
ce in nearly 80% of the patients suggests
t prolonged gastrointestinal decompression is
desirable and that tube gastrostomy may
resent only an additional and unnecessary
erative hazard.

91 MAXIMAL ACID RESPONSE TO HISTAMINE IN
DUODENAL ULCER PATIENTS SUBJECTED TO
SECTION OF THE ANTRUM AND DUODENAL BULB
LLOWED BY VAGOTOMY. (E.) Broomé, A. (Borås
sp., Göteborg, Sweden), H. Bergström and L.
be. Gastroenterology 52(6):952-958, 1967.

A total of 21 duodenal ulcer patients and 5 patients with gallbladder disease were divided into 3 groups according to type of operative procedure. In Group 1, 13 ulcer patients underwent resection of the antrum and duodenal bulb, followed by vagotomy. Group 2 consisted of 8 ulcer patients who underwent pyloroplasty and subsequent vagotomy. Group 3 was composed of 5 cholecystectomy cases which underwent the same preparations for vagotomy as in the others, i.e., a loop of thread was placed around each vagus. Groups 2 and 3 served as controls. Max. acid response of the stomach to histamine (0.024 mg/kg) was determined before and after surgery, and after vagotomy. In Group 1, max. acid response to histamine showed a mean reduction of 51% after resection of the antrum and duodenal bulb; this depressed postresection response was, in turn, reduced by 67% after vagotomy. After resection plus vagotomy, the preoperative max. response to histamine was reduced by an av. of 84%. In Group 2, pyloroplasty alone moderately depressed max. acid response to histamine in all but 1 case; mean reduction was 22%. Vagotomy caused a further decrease, reducing the post-pyloroplasty response by an av. of 51%. As a result of pyloroplasty plus vagotomy the preoperative max. response decreased by an av. of 62%. In Group 3, preoperative and postoperative max. acid responses to histamine were, resp., 12.5 and 12.9 mEq/hr.; variations were minor and no significant differences emerged. These results confirm that resection of the antrum and duodenal bulb significantly reduces the max. acid response to histamine in man, and show that subsequent vagotomy causes a further significant suppression of this response; this indicates that the parietal cell response in man to max. histamine stimulation is facilitated by both basal release of gastrin and direct vagal activation of the parietal cells through a basal flow of vagal impulses.

8292 SURGICAL MANAGEMENT OF DUODENAL ULCER:
EMPHASIS ON VAGOTOMY AND GASTRIC
DRAINAGE. (E.) Pierpont, R. Z. (111 W.
Monument St., Baltimore, Md.), W. K. Brendle,
D. B. Hebb, D. T. Crawford, A. W. Grigoleit and
H. H. Kwak. Amer. Surg. 33(4):334-338, 1967.

Vagotomy and gastric drainage were used for the elective management of peptic ulcer for 12 yr. The 220 patients consisted of 160 men, 60 women; 19-70 yr., av. 50.3. Indications for surgery (number of patients, %, resp.) were: intractable pain, refractory to medical management (126,57.3%); hemorrhage (61, 27.7%); obstruction (23, 10.5%); repeated or previously perforated (10, 4.5%); there were 12 combined gastric and duodenal ulcers. Surgical procedures were vagotomy with pyloroplasty (128,58.2%); vagotomy with gastroenterostomy (78, 35.5%); vagotomy with antrectomy, Billroth I (5, 2.3%); vagotomy with subtotal gastrectomy (6, 2.7%); vagotomy with previous gastroenterostomy (2, 0.9%); pyloroplasty with previous vagotomy (1, 0.4%).

Complications were: pneumonia and atelectasis (3); wound infection (6); wound dehiscence (2); postoperative hemorrhage (1); death (1, 0.45%, due to aspiration of blood in failure to intubate while the patient is awake). Dumping syndrome, wt. loss, and anemia were minimized with conservative management. Flatulence, distention, eructation, and diarrhea were observed in approx. 60% of the vagotomized patients. These were often relieved with bethanechol (15 mg 3 times daily). Symptoms rarely persisted beyond 3 mo. There were 5 recurrences which necessitated reoperation in the form of gastroenterostomy (2), gastric resection (2), and pyloroplasty (1); 4 of these were in the initial pyloroplasty group, 1 gastroenterostomy. There were 3 recurrent symptoms of ulcer in the gastroenterostomy group, all of which responded to simple dietary therapy. The total proven recurrences necessitating reoperation represented a rate of 2.3%. The advantage of recommending early surgery is stressed.

8293 ABO BLOOD GROUP AND SECRETOR STATUS IN STOMAL ULCER. (E.) Langman, M. J. S. (Central Middlesex Hosp., London), R. Doll and R. Saracci. Gut 8(2):128-132, 1967.

Patients of Blood Group O and nonsecretors (persons who fail to secrete ABH antigens in the gastrointestinal mucus) show incidence of stomal ulcers which is higher than the incidence of duodenal ulcers. In the case of nonsecretion, the above difference may be due to the fact that nonsecretion predisposes a patient with duodenal ulcer to come to operation, after which a stomal ulcer may develop. Thus, nonsecretors may not have a greater susceptibility to stomal ulcers. The proper comparison should be between stomal ulcers and those duodenal ulcers that have come to surgery; when this comparison is made, the difference between the 2 series is much smaller and of no statistical significance. In regard to Blood Group O, the situation is less clear; it was found that when patients with stomal ulcers and patients with duodenal ulcers had similar clinical histories, there was no statistical significance in incidence of stomal ulcers in Blood Group O patients. The differences in susceptibility to stomal ulcerations in subjects of various blood groups and nonsecretors is too small to justify taking them into account when selecting patients for any particular type of gastric operation.

8294 PRE- AND POST-OPERATIVE SYMPTOMS OF PATIENTS WITH STOMAL ULCERS. (E.) Jones, J. H. (Central Middlesex Hosp., London) and M. J. S. Langman. Gut 8(2):133-136, 1967.

Patients with duodenal ulcer with previous history of perforation have an increased liability to stomal ulcer, whereas those with a history of pain or obstruction have a comparatively low risk, and those with a history of hemorrhage an intermediate risk of stomal ulce Further evidence shows that patients with blee ing stomal ulcer are particularly liable to ha suffered from a previous bleeding duodenal ulc The association of stomal ulcer with Blood Gro O and ABH non-secretion largely disappears whe the clinical characteristics of previous duode ulcer are taken into account. Therefore, it i likely that it is the clinical characteristics of the duodenal ulcer rather than the ABO bloo group and secretory status of the patient which affect his susceptibility to stomal ulcer.

8295 GASTRIC FIBRINOLYSIS. A POSSIBLE AETIOLOGICAL LINK WITH PEPTIC ULCER. (E.) Cox, H. T. (Withington Hosp., Manchester, England), L. Poller and J. M. Thomson. Lancet 1(7503):1300-1302, 1967.

A study was made of 13 with clinical evidence o chronic duodenal ulceration and 13 who had unde gone upper abdominal operations. Gastric fibrinolytic activity was investigated by takin 2 ml blood directly from a tributary of the lef gastric vein arising in the anterior stomach wall (or from veins arising in the anterior gastric wall towards the greater curvature). Immediately after collection of gastric blood, 5 ml of blood was taken from a peripheral vein. In 3 with duodenal ulceration, additional gastric and duodenal material was obtained duri operation; gastric juice was aspirated from a Ryle's tube and a small portion of gastric and duodenal mucosa was obtained from the specimen excised at pyloroplasty. Standard and modified fibrin plates were used to measure lytic activity, and euglobulin-lysis time was measure Of 13 ulcer patients, 11 showed appreciable zones of lysis in their gastric vein specimens on a standard fibrin plate after 18 hr. of incubation. None of the specimens from the gastric artery or peripheral veins showed a zon of lysis. Of the 13 controls, 5 showed zones o lysis in their gastric vein blood on the standard plate. Of 9 who underwent biliary trac operation, 4 gave positive results; of 2 with malignant ulcer, 1 was positive; of 2 undergoin negative laparotomy, neither was positive. Non of the specimens of blood from peripheral veins showed lysis. In 8 blood was taken from 2 different gastric veins; 6 gave a positive result in 1 specimen, 4 in both specimens; in 6, euglobulin-lysis times were measured and were confirmatory. Free plasmin activity was present in the gastric vein as indicated by activity on heated plates. Saline extracts of gastric mucosa showed lysis on the standard plates only, indicating the presence of plasminogen activator a negative result with this specimen on the heated plate showed the absence of free plasmin. The activity of the gastric juice differed from that of the mucosa, since it was not inhibited by ε-aminocaproic acid; thus the activity was nonspecific proteolysis; 0.1 N HCl alone had no lytic effect; the acid-pepsin mixture caused pronounced lysis, but this was neutralized by

ddition of sodium taurocholate. Anti-
'nolytic drugs may be useful in the treat-
of hemorrhage and also of proved peptic
ration. Bile acts as an anti-proteolytic
t.

EPIDEMIOLOGICAL STUDY OF PEPTIC ULCER
IN THE SOUTH OF INDIA: OBSERVATIONS
MADRAS ON THE CHANGING INCIDENCE OF PEPTIC
R, WITH SPECIAL REFERENCE TO CAUSATION.
Malhotra, S. L. (Western Railway, Bombay).
8(2):180-188, 1967.

emiological aspects of peptic ulcer were
ied in South Indians to determine the signs
symptoms, results of treatment, complications
prevalence of this disease. A total of 469
ents were admitted to the hospital, of which
were treated surgically. The peak age of
ic ulcer was much lower than in the west of
a and a greater degree of cicatrization was
d in operated cases. The incidence of
rrhage, perforation and vomiting was much
er than reported in previous studies; there
also a higher gastric ulcer:duodenal ulcer
o. The reasons for the change in ulcer
vior may be related to changes in eating
ts, higher consumption of bicarbonate-of-soda
elieve dyspepsia and induced vomiting that
oves the HCl, thus weakening the barrier action
ucus and predisposing to ulcers. The
:female ratio was 35:1. This may be
lained by the age structure of the population,
., there were fewer women in the vulnerable
group since most of the women were in the
roductive period of life, when there is less
dency to develop peptic ulcers. Women also
less and took longer over their meals than
in 95% of the families interviewed. Genetic
tors associated with ABO blood groups cannot
lain the change in the ulcer picture, since
important change in blood group distribution
urred. After gastrojejunostomy 3 patients
h duodenal ulcers and low acidities developed
tric ulcers, due to increased duodenal reflex.
er gastrectomy there was complete disappearance
symptoms, gain in wt. and increase in hemo-
bin in most of the patients.

7 PATHOGENESIS OF CINCHOPHEN ULCER OF THE
STOMACH IN THE DOG. (Rus.) Vainshtein,
G. (Med. Inst. Postgrad. Study, Kazan, USSR).
ull. Eksp. Biol. Med. 62(12):50-53, 1966.

e effect of cinchophen (0.2 g/kg body wt.) on
e blood electrolyte level was studied in 3
althy dogs and revealed a disturbance in K
tabolism and in adrenal function. In 1 dog
ich died on the eighth day of the experiment
om cinchophen intoxication, K conc. (in mEq/
ter) increased from 5.2-6.0 to 7.5-7.6. In 2
gs which died on the twenty-first and twenty-
ird day of the experiment, K conc. initially
creased (from 5.2-5.7 to 7.2-7.6, and 5.5-6.5
7.5-7.7, resp.) and was followed by a decrease (in 1 of the 2 after 10 days) to 6.5-6.6 and (in the other) to 4.9-5.3. At autopsy, 1 dog had a massive ulcer in the pylorus; hemorrhages occurred only in the gastric mucous membrane in 2 dogs. A morphologic study showed lesions and a decrease in functional activity of the glomerular zone with a certain increase of function in the nodular zone. The subsequent decrease in K level of the blood was possibly due to repeated vomiting. The disturbance in the K metabolism and decrease in mineralocorticoid function of the adrenal cortex during experimental cinchophen ulceration explains the increase in the gastric secretion, total and free gastric acidity during cinchophen treatment. The data accumulated in this study indicate some similarity in the pathogenesis of experimental cinchophen ulcer and human peptic ulcer.

8298 SYNERGISM BETWEEN COLD AND RESTRAINT FOR RAPID PRODUCTION OF STRESS ULCERS IN RATS. (E.) Senay, E. C. (Yale U. Sch. Med., New Haven, Conn.) and R. J. Levine. Proc. Soc. Exp. Biol. Med. 124(4):1221-1223, 1967.

Female CD rats (180-220 g) were immobilized by a new method (in plastic restraint boxes, described in detail) and then placed in a cold room or refrigerator at 4° or 7°C. Other groups of animals were either 1) restrained in like manner and maintained at room temperature, or 2) refrigerated at 4° to 7° without restraint for a period of 2 hr. before sacrifice. Two hr. later, animals were sacrificed, their stomachs removed and examined for lesions. Of 12 animals subjected to restraint only, none had any gastric lesions. Two (15%) of 13 subjected to cold alone had lesions; 1 (8%) had multiple severe lesions. Of 119 rats subjected to restraint and cold, 79 (67%) had lesions, and 53 (45%) had multiple severe lesions. It is concluded that restraint and exposure to cold acted synergistically to produce gastric ulcers. In addition, restraint using special plastic boxes was found to offer several important advantages over previously described methods. Lesions are produced in 2 hr., there is less variability in the incidence and types of lesions produced, and the animals die infrequently.

8299 PRODUCTION OF DUODENAL ULCERS IN CATS BY INFUSION OF PORCINE GASTRIN. (E.) Emås, S. (UCLA Sch. Med., Los Angeles, Calif.) M. I. Grossman. Gastroenterology 52(6):959-965, 1967.

Porcine gastrin extract, pure porcine gastrin II or saline was admin. by continuous i.v. inj. to conscious, intact cats; the doses of gastrin used were based on studies in other conscious cats with gastric fistulas. Two animals that received porcine gastrin extract for 12 hr. (0.8 g/kg/hr.) in a dose that produced near max. acid and pepsin secretion in cats with gastric fistulas, had a normal appearance of the duodenal and gastric mucosa. In 7 of 8 animals who received the same dose of gastrin extract for 24 hr., ulcers or erosions occurred in the proximal duodenum, with gross bleeding in 4; in addition, 3 animals had ulcers in the pyloric gland region. Two cats that received the same dose of gastrin extract for 96 hr. had duodenal ulcers, 1 with perforation. Neither of the cats had erosions or ulcers in the oxyntic or pyloric gland area. In 4 animals who received 0.2 g/kg/hr. of gastrin extract for 24 hr., duodenal ulcers and erosions were produced in all, but these were less severe than those produced by the larger dose; 2 had small, hemorrhagic ulcers in the oxyntic gland area and 2 had ulcers of similar type in the pyloric gland area. In all of 4 cats, porcine gastrin II infused for 24 hr. in a dose that produced near max. acid secretion in gastric fistula cats (2 μg/kg/hr.), produced severe duodenal ulcers with hemorrhage; none had ulcers in the oxyntic gland area. The pyloric gland area was normal in 1 cat, had multiple erosions in 1, had a very small erosion just proximal to the pylorus in 1 and had multiple, small, rounded superficial ulcers in 1. In cats that received saline i.v. for 12, 24, or 96 hr., the gastric and duodenal mucosa had a normal appearance.

8300 METHODS FOR INDUCING AN EXPERIMENTAL GASTRIC ULCER IN CATS. (Rus.)

Tuldasheva, M. Kh. (Pavlov Inst. Physiol., Acad. Sci., Leningrad, USSR). Biull. Eksp. Biol. Med. 62(11):122-125, 1966.

A study was performed on a total of 70 cats; in the first series gastric ulcers developed in 93.7% of the animals after functional trauma to the CNS (induction of neurosis) and spraying of the gastric mucous membrane with a 0.5% soln. of gastric juice. In the second series, spraying of the gastric mucous membrane with 0.5% of gastric juice alone induced ulcers in 50% of the animals; this was probably due to a somewhat increased conc. of spraying soln. (gastric acidity was 0.25-0.3% HCl). Controls treated with 0.25% soln. of gastric juice revealed no destructive changes to the gastric mucous membrane. In the third series, the admin. of 0.25% soln. of gastric juice in "neurotic" animals resulted in a pre-ulcerative condition and pronounced ulcers in all of the animals; in controls, electric current and a neurotic state had no effect. In cats with a Basov's pouch fistula, 2-2.5 wk. after surgery, changes which were hyper- and hyposecretory in nature occurred in almost all cases; the qualitative composition of the gastric juice was changed in all of the animals. Elimination of the secretion base "interference" (by the Kurtzin modification of the Kriazhew method) was made simultaneously with spraying of the gastric mucous membrane (25 liter of fluid in 2 hr.). After an av. of 22 hr. (10-12 days) of spraying, ulcers appeared and spraying was stopped. The appearance of ulcers was accompanied by an exacerbation of the general condition, anorexia vomiting, emaciation, and in some, the appearan of blood and mucus in the gastric juice. The appearance of ulcers was also accompanied by histomorphological changes of the neurovascular and neuroglandular apparatus. Microscopic examinat of the experimental ulcer of the pylorus reveale lymphocytic infiltration, enlargement of the lymphoid follicles, marked dilatation of the blood vessels, followed by desquamation of superficial epithelial cells, lysis of lymphoid eleme tissue swelling and ulcer formation; morphologi changes in the gastric nerves were of focal and not diffuse character. Thus, this method inclu neural and peptic factors, and resembles the mechanisms which characterize the development of peptic ulcer in man.

8301 INTRAVENOUS DEGRADED CARRAGEENAN AND HISTAMINE GASTRIC ULCERATION IN THE GUINEA-PIG. (E.)

Anderson, W. (U. Strathelyde, Glasgow, Scotland) and P. D. Soman. Nature (London) 214(5090):823-824, 1967.

The absorption of carrageenans, and its stimulation of a protective mechanism in the guinea pig duodenum was studied in an attempt to reproduce the antigastric ulcer effect of degraded carrageenan by i.v. admin. of 2.5 mg/kg of 2 different degraded carrageenans (Eucheuma spinosum and Gigartina pistillata). I.v. admin. significantly reduced experimental histamine gastric ulceration. Although the effective i.v. doses of both carrageenans are equal, intraduodenal admin. of G. pistillata is as effective in preventing gastric ulceration as half the dose of degraded E. spinosum. Dosage of degrade carrageenans varied with the route of admin. Protective effects of both carrageenans coincide with increased acidity of secretion, compared with the histamine group run along with the other 2 groups. Simultaneous i.v. admin. of carrageenan and histamine caused a rise in acid. It appeared that under certain conditions carrageenan can reduce max. acid secretion (histamine), and, under other conditions, can result in an increase of the acid secretion accompanying gastric ulceration, simultaneously providing an anti-gastric ulcer effect. Carrageenan tends to displace the in vivo manyfaceted equilibrium towards the least harmful position.

8302 DUODENAL AND GASTRIC ULCERATION AFTER BURNING. (E.)

Sevitt, S. (Birmingham Accident Hosp., England). Brit. J. Surg. 54(1): 32-41, 1967.

Among 291 patients who died after burning and were submitted to necropsy during 1948-1965 were 26 with acute duodenal ulcers (8.9%) and 42 with acute gastric erosions (14.4%). Statistical analysis indicated a reasonably confident connection between burning and ulceration. Only 4 had lesions in both organs. Duodenal ulceration was

ntly silent in 23 patients but was
ted in 3 because of hemorrhage. One
t died of hemorrhage and another after
ation. The usual location was the posterior
f the first stage and penetration was not
on. One or 2 ulcers were usual and only 4
ts had 3 or more ulcers. Gastric erosions
presented as multiple, tiny, disseminated,
icial lesions suggestive of a specific
, but other kinds were often seen.
ogically, both duodenal and gastric lesions
ften seen colonized by microorganisms,
ally *Monilia* and gram-negative bacilli.
seemed to be invaders from the lumen and
growth *in situ* indicates protection from
Cl or its absence. Colonization by gram-
ve bacilli of the wall of the ruptured
in the case of fatal hemorrhage may have
buted to rupture. Duodenal ulcers were
und within a day of injury nor when the
involved less than 10 or 15% of the body
setting these aside the frequency was 11.9%.
is indicated that duodenal and gastric
occurred either early (during the first
r later, especially in the third and
wk. In children, early duodenal ulcers
nfrequent but later ones were common;
c ulcers were common early and late.
al ulcers seemed less frequent in subjects
od Group A than in Group O subjects.
ce is presented concerning important
ences between duodenal and gastric lesions
tive of different factors in pathogenesis
so of different kinds of gastric erosions.

"CURLING'S ULCER" IN THE GERMFREE MOUSE.
(E.) Einheber, A. (Walter Reed Army
Ctr., Washington, D. C.), R. E. Wren, R. F.
and A. S. Dobek. *Nature* (*London*) 214(5085):
99, 1967.

ree CD-1 mice were randomly divided into 2
s: Group 1 was kept germfree; Group 2 was
ntionalized (contaminated with mixed micro-
flora contained in the cecal contents of
ntionally maintained laboratory mice, with
xception of *Pseudomonas* and *Proteus*);
s 1 and 2 were maintained and handled in
ame way. At 2 mo. after conventionalization
. old), the mice (anesthetized) were burned
mersing the dorsum to the mid-axillary line
the base of the neck to the base of the tail
ter at 76.5°C for 10 sec., giving a third-
e burn over 30-35% of the body surface;
tory orifices and limbs were not burned;
ng was halted by immersion in water at 30°C
0 sec. Steam-sterilized food, which was
before burning, was withheld for 48 hr.,
hen offered to mice housed in 23-25°
tors. Thoracic and abdominal cavities of
d mice that died were opened and exposed to
al buffered formalin; stomachs were opened
the greater curvature and examined grossly
icroscopically; tissue sections were taken
stomachs with lesions, and stained with
toxylin-eosin. The incidence of mice with gastric lesions/total number of mice, in germfree and conventional mice, resp., were: days 0-1, 2/5 and 0/2; 1-2, 7/9 and 11/13; 2-3, 5/5 and 1/3; 3-4, 9/9 and 0/0; 4-5, 5/5 and 1/1; 5-6, 2/3 and 0/0; 6-7, none; 7-8, 0/1 and 0/0. The overall incidence was 30/37 (81%) in germfree, 13/19 (68%) in conventionalized mice. The ulcers were usually grossly visible as multiple foci of hemorrhage; the number and size were not related to the time of death or microbial state; they were restricted to the glandular portion of the stomach and were usually scattered along rugae as discrete, punctate lesions of diameter usually less than 1 mm. It is concluded that the presence of living bacteria is not necessary for gastric ulceration to occur in burned mice.

8304 ACUTE PEPTIC ULCERS IN THE COURSE OF BURNS. (Pol.) Nasiłowski, W. (Inst. Hematol., Warsaw) and Z. Czechowska. *Pol*. *Tyg*. *Lek*. 21(45):1726-1728, 1966.

During 1954-1966, 95 autopsies were performed on subjects with burns; 6 (3 men, 3 women; 20-79 yr. old) had Curling's ulcer (duodenal in 5, gastric in 1). These had 15-35% third-degree surface burns and survived from 11-147 days. Curling's ulcer was the primary cause of death in 3 (from hemorrhage in 1, and perforation in 2). The authors emphasize the diagnostic difficulties which arise from the usually retarded course of the disease and the danger inherent in the use of ACTH and corticosteroids in severely burned cases due to the high risk of ulcer development. The problem of Curling's ulcer is reviewed and discussed from the clinical and pathological points of view.

EFFECT OF DIETARY GLUTEN UPON NEOMYCIN-INDUCED MALABSORPTION. (E.) Levine, (Brooklyn-Cumberland Med. Ctr., N. Y.). oenterology 52(4):685-690, 1967.

ole of dietary gluten in the pathogenesis of cin-induced malabsorption was investigated healthy volunteers receiving daily p.o. . of 2 or 12 g of neomycin during weekly periods. Neomycin, at both dosages, with luten-free diet or the gluten diet, induced ficant and reversible depressions of plasma fatty acids, serum cholesterol and carotene, rinary D-xylose excretion. Diarrhea, wt. and steatorrhea developed only with the dose. During control, experimental, and ery periods of 1 wk. each, with dietary n restriction or supplementation, no altera- were observed in the histology of the normal al mucosa or in the bacteriology of the um, which remained sterile. The data indicate the presence or absence of gluten in the failed to influence the development or extent e malabsorption produced by admin. of neo- for 1 wk.

EFFECT OF ENDOTOXIN ON IRON ABSORPTION. (E.) Cortell, S. (Walter Reed Army Inst., Washington, D. C.) and M. E. Conrad. J. Physiol. 213(1):43-47, 1967.

oxin produced marked abnormalities in Fe ption and metabolism in male albino rats n hr. after the admin. of a parenteral dose. ges observed during the first day after inj. unique; there was decreased absorption of th a normal intestinal Fe content, an acceler- rate of clearance of Fe from plasma, and eased serum Fe conc. That a generalized toxic effect upon the intestine was not the e of these changes was suggested by the normal stinal histology and lifespan of mucosal cells, al absorption of glucose and unchanged ex- ive absorption of Fe by endotoxin-treated, epleted animals. Two days after admin. of toxin, most of the abnormalities had become al, except that the intestinal Fe content eased, and a significant decrease in Fe rption persisted. It was only during this r period that Fe-depleted rats had decreased rption of Fe from the intestine. It is ested that the acute absorptive defect was uced by a decreased capability to transfer Fe the mucosal cell into the body, whereas the defect was associated with impaired entry of aluminal Fe into the intestinal absorptive cells.

LACTOSE MALDIGESTION IN AUSTRALIAN ABORIGINAL CHILDREN. (E.) Elliott, . (Adelaide Child. Hosp., Australia), G. M. ell and N. Vawser. Med. J. Aust. 1(2):46-49, .

Widespread occurrence of stunting, respiratory and gastrointestinal disease was found in 324 Australian aboriginal children less than 15 yr. old at Papunya, Australia and among 62 children (preschool age) at Maningrida. Lactose digestion tests were performed and demonstrated a higher incidence of abnormal test results than could be expected in a similar group of Caucasian children: lactose maldigestion was strongly correlated with age, and to a lesser extent, inversely related to wt. percentile groups. Abnormally low lactase activity (lactase determinations on low duodenal or high jejunal mucosal specimens) correlated well with the results of lactose tolerance tests. Sucrose tolerance and xylose absorption tests were essentially normal in most of the children; in accord with this, pathological examination of the mucosal specimens showed no structural alterations. Hemoglobin levels and serum protein levels were essentially normal. Lactose maldigestion was widespread among these children, but the cause of the defect or its relationship to malnutrition or gastrointestinal symptoms, remains obscure.

8332 AN IN VIVO METHOD FOR STUDY OF INTESTINAL ABSORPTION IN THE UNANESTHETIZED RAT. (E.) Small, M. D. (D. C. Gen. Hosp., Washington), V. Folen and F. I. Marcus. J. Lab. Clin. Med. 69(5):879-884, 1967.

An in vivo technic for repetitive evaluation of absorption in unanesthetized rats is described in detail. A polyvinyl tube is implanted in the duodenum and ileum of rats, and is so localized that it can easily and atraumatically be exposed; it is connected to an infusion and collection system and used in the study of absorption of materials. ^{14}C-Polyethylene glycol (molecular wt. 4000), employed as a nonabsorbable marker to correct for dilution of absorption of the solvent, is simply and automatically determined in a scintillation counter, thus reducing the amount of time and work required for evaluating the remaining nonabsorbable marker to a minimum. This preparation was used in assessing the absorption of xylose and glucose in rats. The xylose which remained was determined by the method of Roe and Rice, and glucose was quantitated by the modified Somogyi method; ^{14}C-polyethylene glycol determinations were made in a Packard Tri-Carb Model 314-EX liquid scintillation counter. This animal preparation showed considerable stability. The animals regained their preoperative wt. within 2 wk. after the operation and continued to gain in a relatively normal fashion up to 5 mo. after the procedure. Absorption values obtained for glucose and xylose indicated that approx. 57% of the glucose was absorbed, while only 10% of the xylose was absorbed. The relative absorption rate (with glucose considered as 100) was comparable to that determined by Cori, with xylose being absorbed 15% as rapidly as glucose.

8333 MALIGNANCY IN ADULT COELIAC DISEASE AND IDIOPATHIC STEATORRHOEA. (E.) Harris, O. D. (Gen. Hosp., Birmingham, England), W. T. Cooke, H. Thompson and J. A. H. Waterhouse. Amer. J. Med. 42(6):899-912, 1967.

A total of 202 patients (108 men, 94 women) with either adult celiac disease (136) or idiopathic steatorrhea (66) were studied to assess the frequency of occurrence of cancer among them. There were 31 malignancies in 29 patients (16 in adult celiac disease patients, 15 in idiopathic steatorrhea patients); 27 were either lymphoma or cancer of the gastrointestinal tract. For the total group, the mean duration of all symptoms was 24.4 yr., and the mean age at time of diagnosis was 39.6 yr.; for those with adult celiac disease, the mean duration of symptoms before diagnosis of lymphoma was 21.2 yr., and of cancer of the gastrointestinal tract, 38.5 yr. Of 77 patients who died, 26 did so from malignant disease. Of carcinomas of the gastrointestinal tract, 4 occurred in patients with adult celiac disease and 9 occurred in 8 with idiopathic steatorrhea; 6 were in the esophagus, 3 in the stomach and 1 each in the tongue, colon, rectum and anus. The collective incidence of gastrointestinal tract carcinoma was 6.4%. In the total group of 14 in whom lymphoma developed, 8 had adult celiac disease and 6 idiopathic steatorrhea; the overall incidence was 6.9%. Of the total 14 lymphomas, 10 were reticulum cell sarcoma (located in jejunum, 6; ileum, 2; stomach only, 1; and extragastrointestinal tract, 1); extragastrointestinal tract Hodgkin's disease was found in 4. It is concluded that both adult celiac disease and idiopathic steatorrhea can be complicated by either lymphoma or carcinoma of the gastrointestinal tract (especially the esophagus); the incidence is highly significant in men, and significant in women. A gluten-free diet appeared to lessen significantly the incidence of malignant complications in adult celiac disease, especially in women.

8334 SELECTIVE IgA DEFICIENCY WITH STEATORRHEA. A NEW SYNDROME. (E.) Crabbé, P. A. (St. Pierre U. Clin., Louvain, Belgium) and J. F. Heremans. Amer. J. Med. 42(2):319-326, 1967.

A 60-yr.-old woman is described with osteomalacia and malabsorption syndrome resembling nontropical sprue. She was given a strict gluten-free diet and vitamins to be taken p.o. with Fe and folic acid supplements. Definite subjective improvement was observed after 1 yr. of the diet, and by this time there was a return to normal values of the hematocrit, hemoglobin conc., proteinemia, fecal fat excretion, and intestinal absorption of D-xylose. A 6-wk. course of gluten challenge was introduced. After this she was discharged on a gluten-free diet with vitamin supplements. During gluten periods, hematocrit, hemoglobin, D-xylose absorption, fecal fat excretion and total serum protein were abnormal. IgA was not detectable in her serum; no trace amounts were detected during the 14-mo. follow-up. IgM and IgG conc. were normal (120 and 1260 mg/100 ml, resp.) at initial measurement and were not repeated. Imm globulins were measured in the following exocri secretions: tears, whole saliva, gastric and intestinal secretions. IgA could not be demonstrated in any of her secretions or in any of those of normals; IgM was detected in normal sa and in her tears and saliva; IgG in all sources in the normal and in the patient. In her intes tinal mucosa, all specimens showed a definite predominance of IgM-containing cells, which wer often tightly packed; the population densities cells containing IgA were always much lower, an in many interstitial areas they were sparse; plasma cells containing IgG were slightly incre in number. The widespread nature of IgA defici suggested that this was the primary event in th patient.

8335 INTESTINAL ULCERATION--A COMPLICATION OF CELIAC DISEASE. (E.) Bayless, T. (Johns Hopkins U. Sch. Med., Baltimore, Md.), R. F. Kapelowitz, W. M. Shelley, W. F. Ballinge II and T. R. Hendrix. New Eng. J. Med. 276(18) 996-1002, 1967.

A diagnosis of adult celiac disease was made on the basis of malabsorption, an abnormal small intestine X-ray pattern, normal pancreatic func tion on a secretin test, and the small intestin biopsy changes characteristic of celiac disease The 37-yr.-old male was placed on a gluten-free diet, with rapid subjective and objective impro ment; he gained 12.2 kg in 4 mo., and fecal fat excretion became normal. He followed the glute free diet for the next 5 yr., having 1 formed stool daily. Repeated intestinal biopsies (0, 6 yr.) showed marked improvement. After 7 yr., a large ulcer abutting the superior mesenteric artery was found at the third portion of the duodenum. Gastrojejunostomy and vagotomy were performed. Hospitalization on a strict gluten-free diet continued for 2 mo. On 60 mg predniso daily, his appetite and sense of well-being increased, his body wt. stabilized, he became afebrile, but leukocytosis continued. Predniso was reduced to 25 mg daily on discharge. He was soon readmitted for intestinal perforation. He died at 44 yr., 10 mo. after onset of abdominal pain. The pathological appearance of the ulcers was entirely nonspecific. The hard, calcified granulomas in the liver and lung were thought to represent previous exposure to Histoplasma. The were no fungi or granulomas in the small intesti and it was considered quite unlikely that the intestinal ulcerations were caused by histoplasm sis. The widespread foci of moniliasis, surroun by acute reactive changes, were a terminal event in a debilitated, cachetic patient receiving adrenocortical steroids. Fifteen other cases from the literature are described with either proved or probable celiac disease in whom multip small intestinal ulcers developed; 12 died as a result of ulceration. These ulcers appear to be complications of celiac disease. They may preve

atient's response to a gluten-free diet
ay thereby obscure the diagnosis of celiac
se.

STEATORRHEA AND MALIGNANT LYMPHOMA.
THE RELATIONSHIP OF MALIGNANT TUMORS
MPHOID TISSUE AND CELIAC DISEASE. (E.)
d, W. I. (Bristol Roy. Infirm., England),

rognosis is poorer.

RESPONSE TO A GLUTEN-FREE DIET OF
PATIENTS WITH THE COELIAC SYNDROME.
(E.) Pink, I. J. (St. Thomas Hosp., London)
and B. Creamer. Lancet 1(7485):300-304, 1967.

Fifty-four patients with celiac syndrome were put on a gluten-free diet; 70% (38 patients) returned to full health. The remaining 30% were divided into 3 groups as follows: 5 patients (with small, severe and extensive intestinal mucosal lesion) who deteriorated after gluten withdrawal, 3 patients (with flat mucosal-biopsy specimens, and pancreatic deficiency) remained chronically ill, and 8 patients who unexplainedly responded only partially to gluten withdrawal. Follow-up ranged anywhere from 6 mo. to 14 yr. Those 38 patients with swift normalization of health became normal within 6 mo., the response clearly starting within 2 wk. in most of the patients (1 died 2.5 yr. later of Hodgkin's disease). The patients who deteriorated (5 patients) were the only ones of the failure group to benefit from steroids. The second group of failures (3 patients) were not improved with steroids. The third group of failures were not given steroids.

HUMAN SERUM ANTIBODIES AGAINST RAT
COLON MUCOSA. (E.) McGiven, A. R.
sh U., Melbourne, Australia), S. P. Datta
.. C. Nairn. Nature (London) 214(5085):288-
1967.

y normal sera, 18 Group 0 (4 men, 14 women;
yr.), 1 Group A (40-yr.-old man), 1 Group
9-yr.-old woman) were examined before and
human RBC absorption. For hemagglutination,
were inactivated by heating at 56° C for
n., and absorbed twice with human A_1 cells
move all hemagglutinating activity for A
; each serum was then further absorbed by a
e treatment with washed sheep RBC. Tests
carried out with equal vol. of absorbed sera
heep RBC sensitized with freeze-dried antigen
red from a phenol water extract of germ-free
eces. For immunofluorescence, quick-frozen
s of rat colon mucosa were cut at 6 μ,
ed by the sandwich method with goat anti-
globulin labeled with lissamine rhodamine B.
era agglutinated with sheep cells sensitized
rat feces antigen. The titer was usually
ed after absorption with A_1 cells; reduction
ot always related to anti-A titer of un-
bed sera. Seven sera gave immunofluorescent
ing of rat colon mucosa. This was partially
mpletely inhibited after absorption with A_1
, but activity persisted in 4 absorbed sera
as strong in 1. Staining both by absorbed
onabsorbed sera was located in the cytoplasm
e mucosal cells and in the intraluminal
. Staining was not closely related to the
A titer or to the hemagglutination titer
the sensitized sheep cells.

EHLERS-DANLOS SYNDROME CAUSING INTES-
TINAL PERFORATION. (E.) Aldridge,
(Wellington Pub. Hosp., New Zealand). Brit.
rg. 54(1):22-25, 1967.

patients with Ehlers-Danlos syndrome are
ly described, 2 with spontaneous perforation
e intestine, 3 with skin lesions only. Two
e latter 3 are sons (10 and 12 yr.) of 1 of
ormer 2. The difficulties to the surgeon
tressed. Treatment of intestinal complica-
should be along routine lines, bearing in
the fragility of the tissues in general and
endency to wound dehiscence and sepsis.
hes should be through more skin and s.c.
e than is normally used, should be tied
ly and should remain in the wound for a
r period than normal.

AN APPLICATION OF TRANSINTESTINAL
INTUBATION TO THE STUDY OF THE COLON.
Torsoli, A. (U. Rome), P. Arullani and
sale. Gut 8(2):192-194, 1967.

irst phase of the technic for studying the
is the conventional end-to-end intubation,
lasting from 48-120 hr. for passage. The second phase is the anterograde or retrograde introduction of instruments. Anterograde introduction did not cause discomfort, alteration in the gut, or bleeding. A constricted tract of intestine is a contraindication. The Crosby capsule was introduced by anterograde transintestinal pilot intubation, and biopsies were performed on the right and left colons in more than 65 patients. This method of intubation also was used to measure intraluminal pressure and pH, and to collect samples. Biopsy, telemetry, or aspiration maneuvers were guided by radiotelevision. Radiotelevision was used on an av. of 5 times per patient, and the individual controls in intubation did not exceed 20 sec., i.e., 0.15 mA/sec. 90KV. During maneuvers, controls with the same values did not exceed 3 min. The total irradiation of each patient, therefore, was not more than 50 mA/sec.

8352 AN OBJECTIVE EVALUATION OF THE ANAL SPHINCTER FUNCTION AFTER SURGERY PERFORMED FOR RECTAL FISTULAS. (Rus.) Nazarov, L. U. Vestn. Khir. Grekov. 97(11):92-97, 1966.

The av. height of the anal canal in 25 healthy women was 2.5-3.0 cm, and in 25 healthy males it was 3.5-4.0 cm. During sphincter malfunction, these indices decreased to about 2.0-2.3 cm. The apparatus for measurement of the function of the anal sphincter included a rubber bulb (to pump air) connected to a glass containing water; the latter was connected to a partially-filled water manometer (filled to the zero point), which was, in turn, connected to a closing T-valve; the second opening of the latter is connected to a monitor with a rubber bulb (which is inserted into the anus) and the third opening is connected to a single-thread cock; this latter is connected to a mercury manometer and a kymograph. In order to study tonus and contraction force, the T-valve is changed to the position in which the monitor is combined with a water manometer. The air vol. did not exceed 24 cm. This device was used on 50 healthy individuals (25 men, 25 women) and on 106 patients operated upon for all types of rectal fistulas; examination was made either directly after surgery, or 1-3 mo. later. In simple fistulas, function of the anus is restored at approx. the twentieth day after operation, and 1.0-1.5 mo. after surgery for transphincter fistulas. In the case of complex fistulas (84 patients), a normalization occurred 2-3 mo. after surgery.

8353 SURGICAL MANAGEMENT OF COLONIC DIVERTICULITIS. (E.) Giffin, J. M. (Washington U. Sch. Med., St. Louis, Mo.), H. R. Butcher, Jr. and L. V. Ackerman. Arch. Surg. (Chicago) 94(5):619-626, 1967.

The results of surgical treatment of diverticular disease of the colon, performed on 170 patients, are presented; recurrent or persistent diverticulitis existed in 88 patients, and the remainder were treated for regional complications of the disease. Among 152 patients undergoing definitive resectional therapy, 120 had primary colectomy (114 with end-to-end anastomosis, 6 without anastomosis), 20 had a 2-stage resection and 12 had a 3-stage procedure. A complementary colostomy proximal to a colonic suture line was used in 5 of 152 resections. Procedures other than colonic resection were done on 18 patients; these included colostomy in 5, adhesiolysis in 3, drainage in 3, oversewed bleeding point and closure perforation in 1 each, exteriorization in 2 and closure of fistula in 3. Perforation with peritonitis occurred in 20 patients, and in 37 others regional abscess was encountered; colonic obstruction existed in 28. Colonic fistula existed in 14. Among 21 patients undergoing emergency colectomy, 11 had resection for massive bleeding, 3 for peritonitis, 4 for colonic obstruction and 4 for perforation with abscess; there were 6 postoperative deaths (29%). The success of operational therapy was primarily related to the presence of inflammatory complications of the disease; other factors which adversely affected the risk of operative treatment were old age (more than 70 yr.), the existence of more than one complication of diverticulitis, attendant medical illness and the use of emergency colectomy. Primary colectomy was a safe procedure among patients having acute uncomplicated diverticulitis. Patients resected in the presence of open pelvic abscess, peritonitis and colonic obstruction sustained complications with great frequency. Resectional therapy for enteric fistula was not curative when pelvic abscess was seen at the definitive operation. When colostomy and drainage was used primarily, the effectiveness of subsequent elective colectomy was reduced among those patients having persistent pelvic inflammation or abscess. Total abdominal colectomy was much more effective than segmental colectomy as therapy for massive colonic bleeding when the primary site of hemorrhage was not identified at operation.

8354 REGENERATION OF THE HUMAN COLON MUCOSA. MORPHOLOGICAL AND HISTOCHEMICAL STUDY.
(E.) Melnyk, C. S. (U. Chicago, Ill.), R. E. Braucher and J. B. Kirsner. Gastroenterology 52(6):985-997, 1967.

A total of 12 colon mucosa lesions with ages of 5, 7, 9 and 14 days were obtained by excision biopsy from 4 healthy male volunteer medical students (23-26 yr. old), with no previous digestive symptoms or known disease; lesions were approx. 0.5 cm in diameter and included variable amounts of muscularis mucosae and submucosa. Specimens were studied morphologically and histochemically; the following 12 tissue enzymes were studied: glucose 6-phosphate dehydrogenase, diphosphopyridine nucleotide- and triphosphopyridine nucleotide-linked isocitric acid dehydrogenases, LDH, α-glycerophosphate dehydrogenase, malic acid dehydrogenase, glutamic acid dehydrogenase, succinic acid dehydrogenase, diphosphopyridine nucleotide- and triphosphopyridine nucleotide-linked diaphorases, alkaline phosph and leucine aminopeptidase. The normal human colon mucosa regenerated by cellular prolifera and differentiation producing new glandular st tures after biopsy. Grossly, the initial lesi (5 days) appeared as superficial ulcers covere with an exudate on a large mound of erythemato inflammatory tissue. Microscopically, the les were sharply demarcated areas of epithelial excision, with some infolding of the surroundi mucosal edges; the muscularis mucosae was abse in all lesions. The surrounding lamina propri had minimal edema and hemorrhage. The base of the lesion consisted of a dense mixture of infl matory cells, fibroblasts, edema, hemorrhage a dilated vascular channels. Single layers of regenerating epithelium were present at the periphery of the lesions, and their growth appe to be dependent on establishment of a granulati tissue base with an adequate vascular supply. The leading cells of the regenerating layer we flat to cuboidal in configuration. At 7-9 days the lesions continued as a central area of ulce tion on an inflammatory mound, with a moderate decrease in the surrounding inflammatory reacti at the periphery, the ulceration had well established regulating epithelial cell layers in progressive stages of transition. At 14 days there was a reduction in the overall gross infl matory reaction and in the size of the central ulceration. In comparison with the 9-day lesi there was a small increase of regenerating epithelium. There was no regeneration of the muscularis mucosae. Normal colon epithelium h no demonstrable leucine aminopeptidase activity and there was no activity in regenerating epith lium. Alkaline phosphatase activity in normal colon mucosa was observed primarily in the lami propria and submucosa, and regenerating single layers and crypts of epithelium had no enzyme activity. Distributions of dehydrogenase activities were generally similar, with minor variations in intensity of reaction. Surface epithelium had greater enzyme activity than the entire crypt epithelium; enzyme activity in the epithelium at the base of the crypt generally w equivalent to, or less than, that in the upper portion of the crypt. However, succinic acid dehydrogenase was an exception to this; it had greater activity in the epithelium at the base of the crypt. Occasionally, lactic acid, malic acid and diphosphopyridine nucleotide-linked isocitric acid dehydrogenases manifested increa activity at the base of the crypt. The normal lamina propria and muscularis mucosae had enzym activity that was considerably less than the surface epithelium. In the distal layer of regenerating epithelium all dehydrogenase enzym had less activity than the normal surface epith lium but activity generally equal to, or greate than, the normal adjacent crypt epithelium. However, succinic acid dehydrogenase activity w considerably reduced. Distribution of the diap orases was similar to that of the dehydrogenase in normal colon mucosa, with max. activity in t surface epithelium and less in the crypts. The regenerating single epithelial layer had less diaphorase activity than surface epithelium, bu vity equal to, and occasionally less than, the cent normal crypt epithelium. Regenerating ts had enzyme activity equal to, or slightly ter than, the surrounding normal crypt epithe- with both diaphorases. An unusual finding he presence of many neutral fat vacuoles ized in the normal surface epithelium and lamina propria; the regenerating tissue total amount of fat that was definitely less than that present in the normal surface elium. It is suggested that the conc. of ochemical tissue enzyme activity at the luminal r in crypt epithelium is not a specific ng limited to one disease entity, but re- s a regenerative phase of colon epithelium.

COLORECTAL ANASTOMOSIS WITH A SUTURING APPARATUS IN RESECTION OF THE RECTUM OLON.

(E.) Rygick, A. N. (Hosp. 67, w), G. M. Juchvidova, V. L. Rivkin, C. R. eva and J. M. Militarev. Gut 8(2):189-191,

paratus is shown for 1-stage suturing of 2 of intestine with a circular mechanical alum) suture with the help of a cylindrical , the anastomosis fold being directed into umen of the intestine. In 100 experiments davers and dogs, the anastomoses were sound atertight with the mechanical suture; wound ng showed less inflammation than with hand ing. The apparatus was used on 60 patients 3 yr.; (mostly women), 42 with high lary or rectosigmoidal cancer of the rectum, of the tumors at 7-15 cm from the anus. All n anterior resection of the rectum with end- d anastomosis by the apparatus. The apparatus troduced through the anus and the ends of esected intestine are fixed onto the suturing of the apparatus with silk pouch sutures. the ends of the intestine are fixed onto pparatus, they are drawn together and then ed by pressing the movable handle of the atus. The cylindrical knife cuts out the d pouch ends of the opposed intestine and nastomosis is made. Anastomosed ends of ntestine after suturing come in contact with external seromuscular membrane; the mucosal s are in the intestinal lumen. Postoperative- had fecal fistulas. Ten were followed for 2 yr. postoperatively; all were well and nastomosis had not narrowed. The apparatus e used for ileorectal as well as colorectal tomosis. End-to-end, end-to-side, and side- d anastomoses were made in 18 with diffuse osis of the colon and rectum and nonspecific ative colitis. The apparatus can be intro- through the anus and through the lumen of igmoid colon and ileum from the abdominal y. All the patients felt well. Use of the atus shortens low anterior resection of the m by 20-25 min.

A COMPARISON OF RECONSTITUTED COLLAGEN SUTURE AND CATGUT SUTURE FOR COLON ANASTOMOSES.

(E.) Adler, R. H. (Buffalo Gen. Hosp., N. Y.), M. Montes, R. Dayer and D. Harrod. Surg. Gynec. Obstet. 124(6):1245-1252, 1967.

Two absorbable chromicized sutures, 1 of conventional catgut and the other of reconstituted collagen, were evaluated in canine colon anastomoses. The reconstituted collagen suture, due to its origin from beef tendon and because it is extruded from a homogeneous dispersion, was inherently more uniform in its physical and biologic properties and therefore more predictable in its behavior than catgut. There was no significant difference in tensile strength of colon anastomoses sutured with reconstituted collagen or catgut sutures at any period from 3 days-8 wk. postoperatively. Histologic study of the healing wound revealed less prolonged inflammatory tissue reaction with reconstituted collagen sutures than with the catgut. The reconstituted collagen sutures were absorbed more rapidly than the catgut sutures, but this did not affect the strength of the anastomosis and was advantageous in shortening the period of tissue reaction. The reconstituted collagen suture had excellent properties of pliability, ease of handling and secure knot tying; they appeared to be superior to catgut sutures in many respects. These properties are desirable in intestinal surgery, since ease of handling of the suture material helps to minimize tissue trauma during surgical repair.

8357 TWO-STAGE RESECTION OF THE COLON.

(E.) Hubbard, T. B., Jr. (U. Maryland Sch. Med., Baltimore), A. Norico and R. A. Harris. Surg. Gynec. Obstet. 124(5):1081-1084, 1967.

A total of 45, three-stage colonic resections were performed during the period 1955-1966; in 28 cases, obstructing carcinoma was the underlying disease and in 17, diverticulitis. The interval between definitive resection and closure of the colonic stoma ranged from 11-355 days, with an av. of 59 days. Hospitalization after stomal closure ranged from 6-34 days, with an av. of 12.6 days. Total inconvenience, the presence of a colonic stoma, additional hospitalization and a further operation therefore involved an av. of 71 days. Complications after closure of the stoma were wound abscess in 5, atelectasis in 1, ileus of more than 5 days in 2, urinary tract infection in 1, and unexplained elevation in temperature to over 100° F for from 3-8 days in 20. During the same period, 23 consecutive patients with lesions of the left half of the colon and rectosigmoid underwent a 2-stage procedure; in 9, the underlying disease was diverticulitis, with either obstruction, perforation or colovesical fistula, and 14 had acutely obstructing carcinomas. No deaths occurred and there were no anastomotic leaks. Postoperative hospitalization ranged from 6-30 days, with an av. of 14 days. The 2-stage procedure is therefore considered to be the operation of choice. The morbidity and expense of colonic stoma as a third operation is appreciable and should not be ignored, especially in obstructing carcinomas, since surgical intervention offers only short-term palliation in most of these patients. In the 2-stage procedure, closure of the stoma at the time of definitive resection reduces the morbidity markedly without increasing the risk. When the 2-stage procedure is performed, transverse colostomy is advantageously done through a midline incision.

8358 THE USE OF TRIETHYLENETHIOPHOSPHORAMIDE AS AN ADJUVANT TO THE SURGICAL TREATMENT OF COLORECTAL CARCINOMA.

(E.) Holden, W. D. (Univ. Hosp., Cleveland, Ohio), W. J. Dixon and J. W. Kuzma. Ann. Surg. 165(4):481-503, 1967.

The use of triethylenethiophosphoramide (thio-TEPA) as an adjuvant to the operative excision of curable colorectal cancer has been evaluated in a collaborative study of 693 patients, of whom 337 (49%) received the drug in 1 of 2 dosage regimens: Regimen 1, 240 (35%) used a total dose of 0.8 mg/kg body wt.; Regimen 2, 453 (65%) used a total dose of 0.6 mg/kg. In the early post-operative deaths the incidence rate of concomitant diseases and postoperative complications were significantly higher than in the remaining patients. In the drug group, excluding 30-day deaths, the incidence rates of postoperative complications by system were not significantly higher than in the controls (120 in Group 1, 236 in Group 2). In Caucasian men (77) the incidence of postoperative complications was higher (49%) than in Caucasian women (68, 36%) or Negroes (19, 35%). The 30-day mortality was 7%, higher than expected. Av. survival time for mortality within 30 days was significantly longer for drug patients (16 compared with 10.5 days). For the early postoperative deaths no significant differences in the mortality rates by causes of death were observed between the control and drug groups. Survival rates for women over 55 yr. in Group 1 were significantly higher for the drug group than for controls for each of the 7 yr. since operation; no significant differences were observed for men in Group 1 or for either sex in Group 2. In Group 1 the survival rates for those without postoperative complications were significantly higher for the drug group than for controls for each yr. since operation. In Group 1 the survival rates for those without positive lymph nodes were significantly higher for the drug group than for controls for the fourth and sixth yr. after operation. In Group 1 the survival rates for those who did not develop recurrence were significantly higher for the drug group than for controls for the second, third, and fourth yr. after operation. In Group 1 the survival rates for those with tumors located in both the colon and rectum were significantly higher for the drug group than for controls for the fourth, fifth, and sixth yr. after operation. The survival rates for the groups with complications, with positive lymph nodes, with serosal involvement, with vessel invasion, with other organs removed, and with recurrence were significantly lower than those for the corresponding group without these characteristics. Survival rates of those not having positive lymph nodes, seros involvement, or vessel invasion were higher tha for those with only 1 of these characteristics; those with 1 had higher survival rates than thos with 2; 2 higher than 3. The lower incidence of recurrence in women was not significantly different from that of men. No significant differences in death rates were found between the control and drug groups by causes of death. There was no difference in the incidence of the presence of cancer at death between the control and drug groups.

8359 OBSTRUCTION IN CANCER OF THE COLON.

(E.) Floyd, C. E. (Louisiana State U. Sch. Med., New Orleans) and I. Cohn, Jr. Ann. Surg. 165(5):721-731, 1967.

Over a 16-yr. period; some degree of obstructio was noted in 512 patients (approx. 33.3%) of 1741 with cancer of the colon, rectum and anus; there were 240 (14%) with complete obstruction and 272 (15%) with partial obstruction. Accura 5-yr.-survival data were restricted to 323 patients admitted from 1948-1958, of whom 146 had complete obstruction and 177 partial obstru tion. The diagnosis of cancer was made in most patients (405) between the ages of 50-79 yr., with the peak incidence in the 60-69 age group. Negroes comprised 58% of the patients. The lef half of the colon was the most common location for both partial (70%) and complete (72%) obstru tions. In partial obstructions, 26% were in the sigmoid and 27% in the rectum; however, with complete obstructions, 43% were in the sigmoid and only 13% in the rectum. The right and transverse colons were infrequently involved. The most frequently associated colonic or recta disease was hemorrhoids, occurring in 81 cases (28 in complete obstruction, 53 in partial obst tion); adenomatous polyps were found in 59 and diverticulosis in 23, each being equally divide between both groups. Histologically, the carcinomas were adenocarcinoma in 191 of 240 cases of complete obstruction, and in 218 of 272 case of partial obstruction; mucoid carcinoma was ne in frequency, with 12 in complete and 18 in partial obstruction, resp. The operative morta for definitive resections was 10% for complete and 17% for partial obstruction. The operative mortality rate for all decompressive procedures was 24%, but the rate for decompression alone w 50%. There were 22 cases with complete obstruction and 34 with partial obstruction who surviv 5 yr., giving 5-yr.-survival rates of 15% and 19%, resp. On the basis of location of the primary lesion, survival rates were poorest for those with complete obstruction in the right colon (7%), transverse colon (0%) and rectum (6 while there was a relatively good survival rate of 22% for those with complete obstruction in th sigmoid and left colon. Survival rates (5-yr.) for those with partial obstruction were about th

(10-29%) with lesions scattered throughout
olon, but were lower for those with lesions
e rectum (4%). The influence of lymph node
vement was evaluated in 139 patients with
ete obstruction and 155 with partial obstruc-
but not all were observed for 5 yr.; there
o lymph node involvement in 42% (122 cases).
yr.-survival rates dropped progressively
44% for those with no nodes with partial
uction to 16% for those with positive nodes
omplete obstruction. When other organs were
ved, there were no 5-yr. survivors. Survival
es ranged from a low of 9% for one-stage
dures in complete obstruction to a high of
or 3-stage procedures in partial obstruction.
study emphasizes the high operative mortality
ow 5-yr.-survival rate with obstructing
r of the colon, rectum and anus.

PROBLEMS IN DIAGNOSIS OF CARCINOMA OF
COLON. (E.) Donald, J. W. (192
elle St., Mobile, Ala.) and J. G. Donald.
Surg. 165(5):705-708, 1967.

case reports are presented to illustrate
requency of delays in the diagnosis of
ic lesions (cancer) due to a negative Ba
X-ray. Six of the 8 were carcinomas of the
which were not diagnosed on first X-ray
; in 1, the lesion was illustrated in the
of 3 Ba enemas because it was filmed in the
position. Two cases described the difficulty
agnosis of multiple carcinomas of the colon.
culty in diagnosis in each case lay in the
ent deficiencies of the usual Ba examination
e colon. Newer technic(s) of Ba enema exam-
on are discussed, the essential features of
include the use of thin Ba with an approx.
fic gravity of 1.120, high kilovoltage
ment, image intensifier, multiple spot films
ineradiography. The thin mixture of Ba
es semitransparent at high kilovoltage,
ing visualization through a loop of Ba-filled
tine, although it is superimposed upon
er. The intensifier increase the brightness
e fluoroscopic image 3-6 x 10^3-fold and
itates the visualization of more detail
ut dark adaptation. The use of cineradiog-
records the fluoroscopic image and permits
w of the findings to arrive at a diagnosis.
technic has been particularly impressive in
emonstration of polyps and early carcinomas.

OBSTRUCTIVE RESECTION FOR ILEUS OF THE
LARGE INTESTINE CAUSED BY TUMOR. (E.)
v, B. A. (Sklifosovskii Inst., Moscow).
ry 61(5):694-697, 1967.

1954-1964, obstructive resection (Hartmann)
leus caused by cancer of the large intestine,
erformed 43 times, including 10 cases com-
ted by perforation of the tumor or rupture
e intestine above it. Patients were 14 men,
men; 25-92 yr., 37 above 51 yr. old. Of 43,
re serious or critical at admission and 23
were operated on within 24 hr., 3 within 48, 1 within 72; in the remaining 16, complete large intestine evacuation could not be achieved. During radical operation, the proximal end above the tumor was found to be distended, and restoration of gastrointestinal continuity by end-to-end anastomosis was ruled out; obstructive resection was performed. Ten had perforative peritonitis caused by perforation of tumor (6), rupture of intestinal wall above the tumor (3), or necrosis of the transverse colon accompanying a tumor of the distal part of the sigmoid colon. Adenocarcinoma was the most common tumor type. The number of deaths per number of operations was: tumor and obstruction, 4 of 28; tumor, obstruction, perforation of tumor, bowel rupture, fecal peritonitis, 8 of 10; tumor, obstruction, and metastasis, 3 of 5. In a comparison, the mortality with the 3-stage Schloffer method for obstruction was 28%, twice that for obstructive resection (4 of 28 = 14.2%). The obstructive resection technic solves 2 problems in 1 stage: elimination of obstruction and removal of tumor. This method has wide applicability. The restorative operation in the second stage after an obstructive resection is not accompanied by special hazards.

8362 ANTERIOR RESECTION AS SURGICAL TREATMENT OF CHRONIC DIVERTICULITIS. (Sp.) Allender, D. (Sao Lucas Hosp., Sao Paulo, Brazil), E. O. Figueroa, J. M. Allende and G. Zabaleta. *Bol*. *Sanat*. *S*. *Lucas* 28(5):77-80, 1966.

8397 COLONIC MOTILITY IN ULCERATIVE COLITIS AFTER OPIATE ADMINISTRATION. (E.) Garrett, J. M. (Mayo Clin., Rochester, Minn.), W. G. Sauer and C. G. Moertel. *Gastroenterology* 53(1):93-100, 1967.

The effect of opium on colonic motility was studied in 15 patients (7 males, 8 females; 15-45 yr. old) with chronic ulcerative colitis, as well as in 10 healthy volunteers (8 males, 2 females; 21-35 yr. old) who served as controls; 10 of the ulcerative colitis patients had involvement of the entire colon, 4 had only left-sided colitis and 1 had colitis limited to the right portion of the colon. To test the effect of the usual clinical dose, 10 drops (0.5 ml) of tincture of opium was admin. p.o. to 10 patients and each of the 10 controls; 5 and 15 drops were used in each of 2 and 3 patients, resp., to observe the dose response to tincture of opium of colonic motility. In 14 patients with mild to moderately severe ulcerative colitis, a single low dose (5, 10 or 15 drops) of tincture of opium produced marked hypermotility of the pelvic colon. A temporal relationship between the start of opiate admin. or increase of dosage and the development of toxic dilatation of the colon was noted in another 17 patients with chronic ulcerative colitis, but a similar relationship to anticholinergics (belladonna, propantheline) was not observed. It is concluded that the hypermotility and increased tonus changes produced by narcotics in patients with chronic ulcerative colitis may bear a relationship to development of toxic dilatation of the colon when these drugs are admin. to patients with the acute fulminating form of the disease.

8398 OBSERVATIONS ON THE INCIDENCE AND CAUSE OF ANAEMIA IN ULCERATIVE COLITIS. (E.) Ormerod, T. P. (Westminster Hosp., London). *Gut* 8(2):107-114, 1967.

A study was made of 479 case records to determine whether low hemoglobin levels have any significance in the histories. In addition, 28 ward patients were studied to determine the role of Fe deficiency, shortening of the RBC life, and the lack of B_{12} in these patients. Anemia was more common in women and in patients with whole colon involvement (colitis). Although the mean corpuscular hemoglobin conc. and the serum albumin level fell with the hemoglobin conc., the degree of anemia was not correlated with the length of the history, age, WBC, RBC sedimentation rate or liver-function tests. Hypoferremia was common. One case was presented in which hemolysis occurred during an acute exacerbation of colitis, and was not associated with sulfasalazine therapy or autoimmune phenomena. These studies confirm the view that Fe deficiency exists in ulcerative colitis.

8399 ELECTRON MICROSCOPY OF THE HUMAN RECTAL MUCOSA. A COMPARISON OF IDIOPATHIC ULCERATIVE COLITIS WITH INFLAMMATION OF KNOWN ETIOLOGIES. (E.) Nagle, G. J. (U. Brazil, Rio de Janeiro) and S. M. Kurtz. *Amer. J. Dig. Dis.* 12(6):541-567, 1967.

Rectal mucosa from 10 patients with ulcerative colitis, 1 with acute colitis secondary to *Shigella flexneri* infection and from 1 patient developed chronic colitis after irradiation the for abdominal Hodgkin's disease, was biopsied a studied by light and electron microscopy. Of those with active ulcerative colitis (9), 3 wer receiving no drug therapy, 4 received predniso and salicylazosulfapyridine and 2 received the latter agent alone. Control biopsies from 3 no volunteers and 2 hospitalized patients without large intestine disease were similarly prepared and studied. By light microscopy, mucosa of al ulcerative colitis patients was generally intac but focal changes ranging from simple distortio and flattening of the epithelium to microulcerations were scattered in the crypts and surface. In the presence of active clinical disease, the lamina propria was variably, but usually heavil infiltrated with acute and chronic inflammatory cells. The mucosa of 1 patient in long-term remission lacked the inflammatory exudate in th lamina propria, although focal degenerative changes were present in the overlying epitheliu By electron microscopy, there was an abundance of dense-walled, small vesicles in the cytoplas of most otherwise-intact epithelial cells in specimens from patients with ulcerative colitis Also, there were focal areas of degeneration, ranging from markedly vacuolated to disintegrat epithelial cells, in the crypts and on the surf Epithelial-cell changes appeared to precede infiltration of the epithelial layer by inflammat cells. So-called "crypt abscesses" were found to consist almost entirely of sloughed, degenerated epithelial cells. Basement membrane remai continuous except in areas of frank ulceration. There was no evidence of bacterial or viral invasion of the epithelium. Steroid and/or salicy azosulfapyridine treatment produced no qualitati differences in the above-described findings. Mucosa from the patient with acute shigellosis had many focal areas of severe degeneration simi in most respects to the changes seen in ulcerati colitis; however, intervening epithelial cells lacked the large number of small, dense-walled vesicles typically present in most of the epithe cells found in material from ulcerative colitis patients. Tissue from the subject with colitis after radiation therapy had few changes in commo with ulcerative colitis and shigellosis. It is concluded that the primary morphologic disturban of ulcerative colitis is widely present in epithelial cells throughout the epithelial-cell layer rather than being limited to the crypts. Similarity of many of the changes observed to those noted in other degenerative and inflammato conditions of the rectal mucosa may signify a limitation in the range of structural response t injury rather than a similarity in underlying pathogenetic mechanisms.

OCULAR COMPLICATIONS OF ULCERATIVE COLITIS. (E.) Billson, F. A. (Gen.
rm., Leeds, England), F. T. De Dombal, G.
inson and J. C. Goligher. *Gut* 8(2):102-106,
.

g a group of patients with ulcerative colitis,
f 465 also had complications affecting the
and 12 of 17 were believed to be a genuine
lication of the colitis (i.e., 7 cases of
cleritis and 5 of iritis). The frequency of
dence among 275 women patients was 3.7%; among
men, it was 2.9%. No complications involving
eye developed during a yr. when the patient
in remission. In almost all instances, com-
ations developed in association with a specific,
re attack of colitis. Among the patients
iritis, 5 of 5 also suffered from "true"
tic arthritis; 3 of 5 (all women), from
losing spondylitis, as well. The mean age
hich ocular difficulties developed was 35 yr.,
ontrasted to a mean age of 31 yr. at the onset
olitis.

8411 A NEW METHOD FOR THE INTRAABDOMINAL MICROSCOPY OF THE TERMINAL VASCULAR BED OF THE RABBIT PANCREAS *IN VIVO*. (Ger.) Heisig, N. (U. Hamburg, Germany). *Z. Ges. Exp. Med.* 142(2):162-174, 1967.

The principle of the method consists of the intraabdominal placement of an optical chamber; the tissue, pancreatic mesentery, is observed through 2 hard, transparent polyvinyl plates, one 2.0 mm thick, corresponding to both stage and slide, the other 0.2 mm, equivalent to the cover glass, removable and held in place within the chamber by means of clamps; 2 cylinders, 1 above, the other below are let into the chamber, their inner ends sealed with cover glasses; the upper cylinder is for the microscope objective and contains the channels for the irrigation of the tissue and thermoelectric junctions for temperature measurement. Either a special microscope condenser with a longer focal distance is used or a fiberglass stub is placed in the lower cylinder for the transmission of light from a conventional condenser to the tissue with some loss in intensity. As magnification increases, the working distance between tissue and objection lens decreases. With this apparatus the least distance between tissue and objective lens lies between 1.0-1.2 mm; special air objectives are required; these lenses have a working distance of several mm approaching the magnification of immersion objectives but having much less resolving power and definition; these are the UMK lenses of the Leitz Co. Proper transducers allow the simultaneous recording of a number of parameters: temperature of the tissues under examination, general body temperature, heart rate, arterial blood pressure, venous blood pressure, electrocardiogram, respiration, acid base balance of the blood cells, and blood cell counts. The method lends itself to photomicrography. One advantage of this method is that physiological factors can be maintained within normal ranges.

8412 PROLONGED AMYLASE ELEVATION. (E.) Ebbesen, K. E. (Lanslasarettet, Ljungby, Sweden) and J. Schönebeck. *Acta Chir. Scand.* 133(1):61-65, 1967.

Ten of 58 patients (17.2%) with pancreatitis had a persistent amylase elevation (over 6 days). In 6 of the 10 a pseudocyst of the pancreas was described; in the other 4 the course followed that of acute pancreatitis. Three other cases with pancreatic pseudocyst were treated, but none had elevated amylase levels and were not included. Pseudocyst was noted in 27 of 69 (39.1%) cases of persistent amylase elevation in the literature. Of a total of 79 cases of prolonged amylase elevation, 33 (40.2%) were complicated by pancreatic pseudocyst. The cause of this prolonged elevation in cases of cyst formation may be: (1) persistent or progressive pancreatitis; (2) diffusion from cystic fluid containing amylase, to serum; (3) pressure effect, the cyst compressing pancreati ducts. The authors favor the last, citing experimental evidence from the literature.

8413 TYROSINE METABOLISM AND FAECAL AMINO-ACIDS IN CYSTIC FIBROSIS OF THE PANCREAS. (E.) Gibbons, I. S. E. (Inst. Child Health, London), J. W. T. Seakins and R. S. Ersser. *Lancet* 1(7495):877-878, 1967.

Of 32 children (8 mo.-16 yr. old) with established diagnosis of cystic fibrosis of the pancreas, 3 long-standing cases were taken off treatment with pancreatic supplements and investigated; 4 new cases were investigated before and after treatment. Controls were 15 normals (2 mo.-14 yr.). All received a normal ward diet and supplementary vitamins. Urine specimens (24 hr.) were collected into merthiolate and stored at 4°C for 24 hr., or deep-frozen and acidified for longer storage. Urinary amino acids were examined by high voltage electrophoresis; phenolic acids were extracted by chromatography (Robinson). Fresh acid urine (10 patients) was tested for p-hydroxyphenylpyruvic acid with 'Phenistix' and reduction of 2,4-dinitrophenylhydrazones to amino acids. Three stools from each patient, collected on separate days, and stools from normals were deep-frozen in solid CO_2 and studied. Stool amino acids were isolated from an acetone extract by 'Zeo-Karb 225 SRC 10' resi Plasma tyrosine conc. 1 hr. before midday meal was determined in 10 patients and 9 normals (Clayton). Phenolic acid chromatograms were also examined for 4-hydroxy-3-methoxymandelic acid. Urinary amino acid patterns were normal in all patients. Av. plasma-tyrosine conc. was 1.6 mg/100 ml in controls, 1.8 in patients; the difference was not significant. Urinary phenolic acids were determined in 21. None showed p-hydroxyphenyllactic acid; all contained p-hydroxyphenylacetic acid, and in 17 of these the level was definitely raised. Tyramine was detected in the stools of the 17 but not in those of normals. p-Hydroxyphenylpyruvic acid was detected in none; 4-hydroxy-3-methoxymandeli acid excretion was normal in all. Stools of all patients with cystic fibrosis, treated and untreated, contained excessive amounts of amino acids, with conc. of leucine, valine, phenylalanine, glycine, proline, and tyrosine being especially high. It is suggested that unabsorbe tyrosine in the lumen of the small intestine is decarboxylated and absorbed when it could be oxidized in the liver to p-hydroxyphenylacetic acid.

8414 AN ANALYSIS OF 600 PATIENTS WITH CARCINOMA OF THE PANCREAS. (E.) Smith, P. E. (Tulane U. Sch. Med., New Orleans,

, E. T. Krementz, R. J. Reed and W. J. Bufkin.
. Gynec. Obstet. 124(6):1288-1290, 1967.

results of treatment of 600 (2.3% of all
ents with cancer) patients with pancreatic
inoma during the period January 1, 1948-
mber 31, 1962 at the New Orleans Charity
ital are presented. The male:female
ratio was approx. 2:1, and for Caucasians it
3:1. Approx. 98% of the patients were over
r. old. The predominant histologic type of
r was the mucin-producing adenocarcinoma;
tumors included islet cell and squamous cell
inomas, and carcinoid tumor. In 13% of
patients, the tumor was confined to the
reas, and in another 31% it was confined to
pancreas and to the regional lymph nodes.
remainder had remote spread at time of
nosis. In 234 (39%) of the patients, the
ase was localized enough to justify curative
alliative operation, but 348 (58%) received
reatment or underwent abdominal exploration.
av. survival for all patients from time of
nosis was 3.2 mo. Only 31 (5.2%) survived
1 yr.; in 5 yr., only 3 patients were alive
2 of these lived for 10 yr. after treatment.
9 patients who had pancreatic-duodenal
ction, 52% died in the hospital. The av.
ival for all patients who had this operation
8.9 mo. compared to 18.4 mo. for those dis-
ged from the hospital. The discharged group
udes 14 patients who survived longer than 1
and 4 who survived 129 mo., 119 mo., 62 mo.,
49 mo., resp. Of 155 patients who had an
ation to bypass the obstructing lesion of
biliary tree, 132 (85.1%) were discharged
the rest died in the hospital. Mean survival
after operation for these patients was 4.7
Patients who left the hospital lived an av.
.3 mo.: 8 lived 1 yr.; 1 lived 36 mo.; 1,
o.; and 1, 21 mo. Patients who had no treat-
survived the shortest time, an av. of 1.8
these included patients who had metastatic
ase unamenable to any treatment. Irradiation,
otherapy or hormones were used on a few
ents, but the av. survival time was not
onged.

HEREDITARY CHRONIC RELAPSING PANCREATITIS:
A CLUE TO PANCREATITIS IN GENERAL? (E.)
:hek, P. J. (Marymount Hosp., Cleveland,
. Amer. J. Surg. 113(6):819-824, 1967.

ıdy of an American family of Anglo-Saxon
stry, represented by 37 members of 5 genera-
; (15 women, 21 men, and a 14-yr.-old boy),
enting a total of 5 cases of hereditary re-
ing pancreatitis, indicated that this disease
echanical and therefore amenable to surgery.
cerature review of pancreatitis in children,
of hereditary relapsing pancreatitis revealed
efinite metabolic disorder underlying either
ition, although the most advanced case among
37 in this study showed an abnormal glucose
rance curve. It was suggested that the in-
ted defect is hypertrophy of the sphincter of
, in association with a common ampulla for
ary and pancreatic ducts. This study also
mpts to clarify the development of pancreatitis
ersons without bizarre or unusual dietary
ts, or with no history of alcoholism. The
ing of pancreatitis in some alcoholic persons
not in others suggests that pancreatitis re-
s from hypertrophy increased by spasm incident
lcohol, with fibrosis later. Disturbed func-
of the gallbladder was not believed to occur
r section of the sphincter if the gallbladder
ormal at the time of sphincterotomy.

PROTEINASE INHIBITOR AND TREATMENT OF
ACUTE PANCREATITIS. AN EXPERIMENTAL
Y. (E.) Dos Reis, L. (U. Coimbra, Portugal).
. Surg. 33(4):311-316, 1967.

groups of dogs were used in this double-blind
y. In Group 1, 6 were inj. with sterile
ne i.v. before and after laparotomy when 8 ml
ile was inj. into the resp. accessory pan-
tic duct. Group 2 (6) was similarly treated:
ead of saline, Trasylol was inj. i.v., 10,000
fore and 5000 U after laparotomy. Group 3 (6)
treated similarly; Trasylol was inj. i.v.
re the operation and either a slow drip of
00 U of proteinase inhibitor in 1000 ml
ne followed it (2) or 5000 U were inj. i.v.
y 4 hr. for 3 doses (4). In Group 4 (4) an
mpt was made to produce acute pancreatitis by
s of a standard Pfeffer preparation; only 1
ed small foci of pancreatic necrosis, while
d a suppurative pancreatitis with interstitial
ammatory infiltrations and microabscesses,
out necrosis or hemorrhage; this preparation
abandoned. In Group 1, 5 had severe lesions
cute pancreatic necrosis, 1 had mild lesions;
roup 2, 3 had severe pancreatic necrosis,
d milder lesions; in Group 3, 5 had severe
reatic necrosis, 1 had milder lesions. The
einase inactivator did not change the nature
degree of lesions of experimental acute bile
reatitis. More work is recommended to assess
value of proteinase inhibitors in acute pan-
titis.

8448 ALPHA CELL HYPERPLASIA IN CALCIFIC PANCREATITIS ASSOCIATED WITH HYPERPARATHYROIDISM. (E.) Paloyan, E. (U. Chicago, Ill.), A. M. Lawrence, F. H. Straus, II, D. Paloyan, P. V. Harper and D. Cummings. J.A.M.A. 200(9):757-761, 1967.

These 15 autopsy cases, along with experimental laboratory studies, indicate a relationship between glucagon secretion and parathyroid function. The authors propose the theory that in some cases of chronic pancreatitis the sustained elevation of circulatory glucagon leads to a reactive parathyroid hyperfunction, secondary to the hypocalcemic effect of glucagon, and that this chronic stimulation of the parathyroids could result in hyperplasia or adenoma formation. Evidence indicates that pathologic changes occur first in the pancreas. A reactive hypersecretion of glucagon is suggested, secondary to hypercalcemia, in cases of primary hyperthyroidism not associated with pancreatitis. Conspicuous hypertrophy and hyperplasia of the islets in 12 of 15 cases of parathyroid adenoma or carcinoma (at autopsy) indicates that hyperthyroidism may induce hyperplasia of the islets of Langerhans. In some cases of the pancreatitis syndrome associated with hyperthyroidism, chronic pancreatitis may precede and predispose to hyperthyroidism.

ANTIBODIES TO CYTOPLASMIC ANTIGENS IN
PRIMARY BILIARY CIRRHOSIS AND CHRONIC
: HEPATITIS. (E.) Paronetto, F. (Mt. Sinai
led., New York, N. Y.), F. Schaffner and
oper. J. Lab. Clin. Med. 69(6):979-988, 1967.

ncidence, classification and diagnostic
ficance of cytoplasmic antigens and their
odies were investigated with the fluorescent
ody method in 136 patients. Antibodies were
ved in 79.2% of 53 sera from patients with
ry biliary cirrhosis, 80% of 15 sera from
ic active hepatitis patients, 16.6% of
a from patients with cholestatic viral
itis, 75% of 4 sera from patients with drug-
ed hepatitis, and 14.2% of 7 sera from pa-
s with systemic lupus erythematosis. Five
disease groups showed no antigens, nor did
ontrols. The cytoplasmic antibodies lacked
or species specificity; they were readily
to a wide variety of both human and animal
es, with the best binding obtained with
, monkey and rat stomach; rhesus submaxillary
; and human hyperplastic thyroid sections.
ntibodies were complement-fixing, distributed
l immunoglobulin fractions, and were adsorbed
e more particulated subcellular liver frac-
. They did not correlate with antibodies
ted serologically by complement fixation. It
oncluded that these antibodies are significant
e diagnosis of primary biliary cirrhosis and
ic active hepatitis. Together with other
ologic changes seen in these diseases, they
aid to indicate a complex alteration of the
e system.

DIFFICULTIES IN DIFFERENTIATING AMEBIC
FROM PYOGENIC LIVER ABSCESS. (E.)
R. P. (U. Texas Southwestern Sch. Med.,
s), J. D. Lehmann and J. P. Sanford. Arch.
n. Med. (Chicago) 119(1):69-74, 1967.

medical records of 39 patients with macroscopic
r abscesses (24 pyogenic and 15 amebic) were
ied. Of the 15 amebic abscess patients, 14
younger men (mean age 40) each with a single
on in the right lobe. The older men (51 mean,
edian) in the pyogenic group (13 men and 11
n) showed only 2 cases of single lesion among
20 cases which could be determined, and 18
s of multiple lesions among those 20. Of the
ents with amebic abscess, 80% were under 50 yr.
ge, and 67% of the patients with pyogenic
ess were 50 and older. Eighteen patients with
enic abscess had both lobes of the liver af-
ed. The patients' age and sex appeared to
orrelated with the type of abscess, and may
f some value in differential diagnosis
een the 2 types. The site also may aid
nosis: single amebic abscess lesions oc-
ed in the right lobe, with 1 exception;
iple pyogenic lesions occurred in both lobes,
10% exception.

8462 MEMBRANOUS OBSTRUCTION OF THE HEPATIC SEGMENT OF THE INFERIOR VENA CAVA. (E.) Rogers, M. A. (U. Witwatersrand, Johannesburg, South Africa), E. Chesler, L. Du Plessis, N. Joffe and E. Joubert. Brit. J. Surg. 54(3):221-225, 1967.

Four cases of membranous obstruction of the hepatic segment of the inferior vena cava are described. In a 37-yr.-old male, an obliquely set membrane in the right atrium was identified and pierced after opening of the atrium. Postoperatively, the jaundice, ascites, and edema gradually disappeared and a venogram showed a patent inferior vena cava. He died 4 yr. later in hepatic coma, and complete obstruction of the inferior vena cava was observed at autopsy. In a 25-yr.-old female, a membrane at the level of the diaphragm was pierced in a similar manner and recovery was uneventful. Two patients refused surgery. The well-developed collateral veins which surround the site of obstruction make direct exposure of the inferior vena cava through an abdominal or thoraco-abdominal incision hazardous, due to possible uncontrollable hemorrhage. The recommended procedure involves excision of the membrane under direct vision, with the aid of cardiopulmonary bypass. The inferior vena cava should be drained by a catheter introduced into the femoral vein and moved to the site of obstruction. The superior vena cava should be drained by a catheter introduced through the right atrium and arterial perfusion performed by cannulation of the femoral artery. The occluding membrane can then be visualized by opening the right atrium. Palpation of the drainage catheter in the inferior vena cava will give accurate assessment of the thickness of the obstructing membrane.

8463 ELECTRON MICROSCOPY OF THE LIVER IN NON HEMOLYTIC ACHOLURIC JAUNDICE WITH KERNICTERUS (CRIGLER-NAJJAR) AND IN IDIOPATHIC CONJUGATED HYPERBILIRUBINEMIA (ROTOR). (E.) DeBrito, T. (U. Sao Paulo, Brazil), M. A. Borges and L. C. DaSilva. Gastroenterologia (Basel) 106(6):325-335, 1967.

Ultrastructural findings in liver biopsies from a 6-mo.-old white girl with Crigler-Najjar syndrome are compared with those of a 24-yr.-old white woman with Rotor's syndrome. Optical microscopy of specimens from both cases appeared normal, with an absence of Fe pigment. Electron microscopy in the first case revealed mild pathology: some enlarged, edematous and distorted microvilli, with a faintly electron-dense matrix, projecting into Disse's space. Rarely, organelles resembling mitochondria were detected inside the space. Kupffer's cells seemed slightly enlarged. Electron microscopic study of liver biopsies from the patient with Rotor's syndrome showed hepatic cells in some areas were scarce or distorted because of edema. Many mitochondria were of irregular size and shape, showing fibrillary degeneration. Some mitochondria showed focal areas of desiccation of the matrix. Some pathological cristae were seen. No definite correlation is drawn between ultrastructural changes and abnormal bilirubin uptake in the patients, a striking variation in conjugated bilirubin proportions, and significant increase of indirect bilirubin, although it is suggested that the abnormality may be partially due to changes in the microvilli of the hepatic cell sinusoidal pole.

8464 SUCTION DRAINAGE OF THE SUBHEPATIC AREA AFTER CHOLECYSTECTOMY. (E.) Clemente, C. and B. Manno. Amer. J. Surg. 113(6): 853-855, 1967.

A modified Hemovac apparatus provided active, continuous, closed suction drainage of the subhepatic space in 61 patients recovering from biliary tract surgery. The plastic tube of the apparatus was cut in half, providing 2 tubes with multiple perforations on the inner 6-8 inches of each. Each half was then brought through the abdominal wall through a separate puncture, and the perforated portions of the tubes so arranged that drainage holes extended from Morison's pouch up through the gallbladder bed. Patients seemed more comfortable with the dry and odorless abdominal dressing, seemed to require less analgesics, and seemed to present less postoperative febrile response. No wound infection occurred. Dressing changes were not needed until approx. the fifth day, when the drainage tubes were removed. No postoperative nasogastric suction was required in those patients. During the 5 days of suction, the vol. of drainage decreased gradually from approx. 150 ml to 20-50 ml/day, and the color changed from bright-red to clear and serum-like. No disadvantages were noted, except the added expense of the Hemovac apparatus. No scar resulted from the punctures where the tubes entered through the skin.

8465 HAEMOCHROMATOSIS AND HEPATIC XANTHINE OXIDASE. (E.) Mazur, A. (Cornell U. Sch. Med., New York, N. Y.) and M. Sackler. Lancet 1(7484):254-255, 1967.

Eighteen human liver biopsy samples, in 3 groups, were microfluorometrically analyzed for xanthine activity to determine whether a failure of xanthine oxidase to appear normally in the liver might lead to excessive deposits of Fe such as is seen in hemochromatosis. The range of values in the control samples (obtained during surgery or at necropsy from patients without liver disease), was 1.81-5.49 μmoles of substrate oxidized/g tissue protein/hr. The range of values in biopsy samples from cirrhotic patients was 1.01-0.00. In biopsy samples from patients with idiopathic hemochromatosis it was 1.46-0.00. No xanthine-oxidase activity was detected in 3 of 6 and 1 of 5 specimens, resp., in the last 2 groups, above. The data suggest that idiopathic hemochromatosis is genetically determined, and is characterized by the failure to develop normal levels of hepatic xanthine oxidase activity.

8466 THE ISOENZYMES OF LACTIC DEHYDROGENASE II. PULMONARY EMBOLISM, LIVER DISEASE THE POSTOPERATIVE STATE, AND OTHER MEDICAL CONDITIONS. (E.) Trujillo, N. P. (George Washington Univ. Hosp., Washington, D. C.), D. Nutter and J. M. Evans. Arch. Intern. Med. (Chicago) 119(4):333-344, 1967.

The serum activities of SGOT, SGPT, total LDH, LDH isoenzymes (LDH 1, LDH 2, 3, 4 combined, an LDH 5), total bilirubin, alkaline phosphatase, and thymol turbidity, were serially determined in 30 patients with pulmonary embolism or infarction. In addition, these parameters were assessed in 80 patients with a variety of disorders including liver disease, the postoperati state, paroxysmal cardiac arrhythmias, and congestive heart failure. The changes in serum enzyme activity following uncomplicated pulmona embolism are variable and nondiagnostic. It appears that many factors may be responsible fo the enzyme abnormalities noted. Pulmonary infarction in patients with chronic congestive heart failure produced immediate striking increases of SGOT, SGPT, and LDH and the LDH isoenzymes. The predominant isoenzyme abnormal occurred in the hepatic fraction LDH 1. LDH isoenzyme fractionation is of value in the detection of postoperative myocardial infarctio and in the assessment of enzyme abnormalities in the postoperative period. Nonspecific chang in enzyme activity were noted following acute medical and surgical conditions. These changes may be related to an increase in hepatic enzyme activity as a response to acute stress. Determination of total LDH and in particular LDH 1 is a sensitive index of neoplastic involvement of the liver.

8467 EFFECT OF THE INJECTION OF ALBUMIN INTO THE SUBARACHNOID SPACE OF THE COMMON DUCT-LIGATED DOG. (E.) Laks, M. M. (Cedars-Sinai Med. Res. Inst., Los Angeles, Calif.), I. J. Pincus and D. Garner. Gastroenterology 52(4):662-666, 1967.

Jaundice was induced in 7 dogs by doubly ligatin and severing the common bile duct. Approx. 7-14 days were required for the serum bilirubin conc. to stabilize. A polyethylene catheter was then inserted into the subarachnoid space. Spinal fluid samples were subsequently obtained from the unanesthetized dog. Dog albumin, fraction V (0.1-1.0 g) was placed in a soln. of 3.5-5.0 m of recipient's spinal fluid prior to inj. After inj. a small aliquot was withdrawn for chemical analysis of albumin, total protein, and bilirubin. Spinal and serum albumin, total protein, and bilirubin were determined daily. In the 7 dogs, a repeated and consistent elevation in the bilirubin conc. was observed in the spinal fluid after inj. of 0.9-1.0 g albumin. The

bin conc. reached a peak level in the second
rd day and then required as long as 19 days
urn to the control level. The bilirubin re-
elevated for as long as 10 days after the
n conc. returned to normal. The serum bili-
did not change significantly during the
of rise of spinal fluid bilirubin. The
ly increased bilirubin:albumin ratio on
may have been the result of either an in-
in the albumin-binding capacity or an al-
on in the permeability of the blood-spinal
barrier, or both. Further studies on the
of lowering the serum albumin conc. in
ain and spinal fluid are suggested.

KETOGLUTARATE TOLERANCE TEST IN LIVER
DISEASE. (E.) Barak, A. J. (VA Hosp.,
Nebr.), H. C. Beckenhauer and M. A. Quaife.
enterology 52(4):655-661, 1967.

mental subjects were normal human, cirrhotic
, normal dogs and Eck fistula dogs. Blood
a and α-ketoglutarate were measured. To
simultaneous ammonium tolerance and keto-
ate tolerance curves in both dogs and man,
g, basal samples of venous blood were taken.
um citrate (0.5 mmole/kg body wt.) was
p.o. to subjects and blood samples were
hourly for a 3-hr. period and analyzed for
a nitrogen and ketoglutarate. In experiments
ed to identify the site of conversion of
e to α-ketoglutarate, the vena cava was
erized with a fine polyethylene catheter
oint just beyond the junction with the
c vein; basal blood samples were taken from
epatic vein area and from the portal vein;
te (as above) was inj. into the lumen of
uodenum; hepatic vein and portal vein samples
taken at 0.5, 1, 1.5, 2, and 3 hr. following
te admin. and all samples were analyzed for
lutarate. Citrate feeding produced a tem-
y rise in blood ketoglutarate; in all cases,
l blood showed a very high conc. of keto-
rate following citrate admin., which fell to
normal within 3 hr. Ketoglutarate is taken
the liver, but not completely even in the
l dog; the intestine is responsible for the
rsion of citrate to ketoglutarate and it is
ed into the portal system in this form.
lutarate tolerance curves in normal dogs
higher than in normal humans, but followed
ar patterns. The most abnormal curves were
ned with the Eck fistula, and all cirrhotic
nts studied showed abnormally high curves
compared with normal humans. Thus the cir-
c liver is hampered in removing ketoglutarate
the blood stream, possibly because of liver
damage or extensive collateral circulation.

CHRONIC FAMILIAL HYPERBILIRUBINEMIA.
HEPATIC DEFECT(S) ASSOCIATED WITH
T HEMOLYSIS. (E.) Dollinger, M. R. (San
cisco VA Hosp., Calif.), L. L. Brandborg, V. E.
or and J. M. Bernstein. Gastroenterology
):875-881, 1967.

A 48-yr.-old male is presented who exhibited Rotor's syndrome of chronic idiopathic jaundice with direct hyperbilirubinemia, BSP retention, and normal liver histology. He also had a slightly shortened RBC survival. The apparent onset of jaundice was coincident with a well-documented episode of viral hepatitis in 1942. Fractionation of the retained BSP (46-53%) showed that it was mostly unconjugated. Three of his 5 children showed slight shortening of RBC survival, indirect-reacting hyperbilirubinemia out of proportion to the degree of hemolysis, and elevated BSP retention. It is suggested that the patient's defects in bilirubin and BSP uptake, as well as the low grade hemolytic process, were transmitted to the children, probably as an autosomal dominant. At the present time the children do not show an excretory defect.

8470 THE EFFECTS OF PORTACAVAL SHUNT AND PORTAL FLOW OCCLUSION ON CANINE AUXILIARY LIVER HOMOTRANSPLANTS. (E.) Tretbar, L. L. (Cleveland Clin. Found., Ohio), E. G. Beven and R. E. Hermann. Surgery 61(5):733-738, 1967.

Experimental transplantation of the liver involves either the orthotopic method, in which the host's liver is removed and replaced with a donor's liver, or the heterotopic method, in which an auxiliary liver is transplanted into another region of the host's abdominal cavity without removal of the primary organ. In the latter method, there is a tendency for progressive atrophy of the transplanted liver, nourished as it is by systemic blood. To eliminate this tendency, an end-to-end portacaval shunt that diverts portal flow around the primary liver was tried successfully in dogs. By means of this method portal nutrition is made available to the transplanted organ from the systemic circulation. Immunosuppressive drugs were used for their effect in preventing rejection of the donor liver. The diseases in which an auxiliary liver transplant might be employed most effectively are those of chronic, progressive hepatic failure of a nonmalignant nature such as progressive active hepatitis, congenital biliary atresia or advanced cirrhosis of the liver. In instances of malignant hepatoma, the liver would require removal following the installation of an auxiliary liver. The present study confirmed the need for both adequate blood flow through an intact portal circulation and adequate portal nutrition in order to prevent the atrophy of auxiliary liver homotransplants.

8471 PHARMACODYNAMIC OF INTRAHEPATIC CIRCULATION IN SHOCK. (E.) Mahfouz, M. (U. Alexandria, Egypt) and G. Aida. Surgery 61(5):755-762, 1967.

The hemodynamic burden on dog liver during shock was studied by open circuit perfusion in the denervated, anatomically-isolated, in situ organ. In each experiment the liver was perfused simultaneously through both the hepatic artery and the portal vein; the perfusate being collected from the hepatic vein. This system was tested a few times for equilibration, which was seen to be immediate. No outflow block phenomenon was observed. Control values were recorded for each experiment. The design of this perfusion system permitted the measurement of the effect of any substance on the hepatic artery, the portal vein, and the hepatic vein separately. Results showed that histamine plays the most effective role in shock, increasing both hepatic and portal vein resistance but leaving undisturbed the hepatic arterial flow, even in high conc. The increase in hepatic vein resistance was much more marked than that of the portal vein. The liver becomes swollen as a consequence of its inflow being greater than its outflow. Epinephrine and norepinephrine increased hepatic arterial and portal venous resistances but had no effect on portal vein outflow ratio. Pitressin was seen to decrease both hepatic arterial flow and portal venous flow and to increase portal vein outflow ratio. Serotonin diminished hepatic arterial flow, portal venous flow, as well as portal vein outflow ratio. Previous studies of hepatic circulation only utilized methods which measured total hepatic flow. The present experiment demonstrates the active role played by vasospastic substances in increasing intrahepatic vascular resistance in shock, a cause of its irreversibility.

8472 STUDIES ON HEPATIC EXCRETORY FUNCTION. III. EFFECT OF HYPOPITUITARISM ON THE HEPATIC EXCRETION OF SULFOBROMOPHTHALEIN SODIUM IN MAN. (E.)

Schmidt, M. L., L. M. Gartner and I. M. Arias (Albert Einstein Coll. Med., New York City). Gastroenterology 52(6): 998-1002, 1967.

BSP metabolism was studied in 8 patients (5 men, 3 women; 24-65 yr. old) with hypopituitarism of varied etiology; the hormonal derangement common to the group of patients was deficient growth hormone secretion which resulted from primary deficiency of the growth hormone (2 patients), Sheehan's syndrome (1 patient), surgical hypophysectomy (2 patients) and pituitary irradiation (3 patients). The mean relative hepatic storage capacity (65.8 ± 41) did not significantly differ from that observed in normal subjects (61 ± 18). The Tm_{BSP} was significantly reduced in each patient and ranged from 2.1-5.8 mg/min., with a mean 4.36 ± 1.2 as compared with a mean Tm_{BSP} of 7.6 ± 1.7 in normal subjects; the mean hepatic transport max. was reduced to 43% of normal. There was an increased ratio of conjugated to total BSP in plasma in the patients. These findings suggest that growth hormone deficiency in man probably reduces the capacity of the parenchymal liver cell to excrete BSP into the bile, and support the hypothesis that growth hormone may play an important role in the regulation of hepatic excretory function.

8473 HEPATIC ALCOHOL DEHYDROGENASE IN ALCOHOLIC ADDICTS WITH AND WITHOUT HEPATIC DAMAGE. (E.)

Ugarte, G. (U. Chile, Santiago), M. E. Pino and I. Insunza. Amer. J. Dig. Dis. 12(6):589-592, 1967.

Hepatic alcohol dehydrogenase activity was measured in liver homogenates from 43 subjects; of these, 6 were moderate drinkers without liver disease who had uncomplicated cholelithiasis or functional dyspepsia. The remaining 37 had a long history of alcohol addiction ranging from 3-24 yr., with an av. of 15 yr.; 28 were invetera drinkers and 9, intermittent alcoholics. None had signs of severe liver failure (jaundice, ascites and coma), and prothrombin conc. was above 60% in all of them. Histologic examination of the liver revealed septal cirrhosis in 6, moderate to severe steatosis in 13, and in the remaining 18 there was either a normal histologic picture or some very slight, nonspecific abnormalities, such as small areas of inflammation or degeneration. Hepatic alcohol-dehydrogenase activity was 0.37 ± 0.12 μM/hr./mg of protein in normal controls, 0.18 ± 0.13 μM/hr./mg in alcoholics with normal liver histology, 0.12 ± 0.09 μM/hr./mg in alcoholics with fatty liver, and 0.12 ± 0.08 μM/hr./mg in patients with alcoholic cirrhosis. Alcohol dehydrogenase was significant lower among alcoholics. There was no difference in the activity of this enzyme between alcoholic patients with liver damage and those without liver damage.

8474 NEW OBSERVATIONS BY LIGHT MICROSCOPY ON LIVER HISTOLOGY IN THE HURLER'S SYNDROME. A NEEDLE BIOPSY STUDY OF 11 PATIENTS UTILIZING PLASTIC-EMBEDDED TISSUE. (E.)

Callahan, W. P. (U. Florida Sch. Med., Gainesvill R. L. Hackett and A. E. Lorincz. Arch. Path. (Chicago) 83(6):507-512, 1967.

Menghini needle liver biopsy specimens from patients with Hurler's syndrome (lipochondrodystrophy or gargoylism) were evaluated by light microscopy, using 0.5 μ-2.0 μ thick, osmium-fixed, plastic-embedded sections as well as routinely processed paraffin tissue. Observations of the liver in Hurler's syndrome demonstrated the following characteristic features: diffuse, discrete vacuolization of hepatocytes; variation in vacuole size, the largest being in periportal areas; vacuolar involvement of the Kupffer cells; prominent sinusoids which are distended with a blue-gray substance demonstrable by toluidine blue staining; and the presence of intact mitochondria and nuclei. The greater resolution obtained by use of plastic embedded sections as an adjunct to examination of routine paraffin sections is emphasized as a valuable technic. Since a tissue specimen measuring only 0.125 mm^3 is required for plastic embedding, the method ideally accomodates the tissue obtained by needle biopsy technics.

8475 URINARY LIPASE EXCRETION IN PANCREATIC AND HEPATOBILIARY DISEASE. (E.)

Pfeffer, R. B. (New York U. Med. Ctr., N. Y.),

hman, T. Cohen, M. Tesler and A. R. Aronson.
Gynec. Obstet. 124(5):1071-1074, 1967.

y lipase excretion (secretin stimulated)
termined in 12 normal controls and in 113
ts who had jaundice or suspected pancreatic
matory disease or cancer; the second group
jects included 9 with established chronic
atitis and 11 with acute viral hepatitis.
normals, after secretin stimulation, there
rise in urinary lipase to an av. value of
/ml (range 0.32-1.7 U/ml), usually in the
r. postinj. period. In 17 patients with
oma of the body and/or tail of the pancreas,
-hr. urinary lipase excretion curve was
ally low in 15 and normal in 2. In 22
ts with chronic recurrent pancreatitis, the
was abnormally low in 20 and normal in 2.
patients with obstructive jaundice, the
as abnormally low in 35 and normal in 12.
patients with acute viral hepatitis had
curves. In 9 other patients with other
y-pancreatic disease, there were 2 with
pancreatitis (1 abnormally low curve 5
fter admission), 3 with pancreatic pseudo-
(1 abnormally low curve) and 1 with acute
with chronic cholecystitis, all with normal
. Seven of 8 patients who were not jaundiced
o were suspected of having malignant disease
pancreas had normal urinary lipase excre-
urves. Serum amylase levels in fractional
s of blood done simultaneously showed no
ation with urinary lipase values. It is
ded that, within certain limitations, the
urinary lipase excretion test is an adjunct
diagnosis of pancreatic carcinoma.

STUDIES ON THE PATHOGENESIS OF TETRACYCLINE-INDUCED FATTY LIVER. (E.)
, M. (U. Texas Southwestern Med. Sch.,
), S. Schenker and B. Combes. Amer. J.
Dis. 12(5):429-438, 1967.

ant and nonpregnant female rats were infused
tetracycline (10 mg/100 g) daily for 3 days.
at time, mean total hepatic lipid and tri-
ride conc. for the tetracycline-inj. non-
ant and pregnant rats were significantly
r than control values. The total lipid and
yceride levels, as well as plasma decay rates
epatic conc. of tetracycline, were comparable
tetracycline-inj. nonpregnant and pregnant
Hepatic ATP levels were normal in animals
tetracycline for 3 or 7 consecutive days
ll as in those studied during max. hepatic
cycline conc. It is concluded that in the
tetracycline-induced fatty liver is not
ted via hepatic ATP depletion; large doses
tracycline are metabolized comparably and
t in a similar increase in hepatic lipid in
ant and nonpregnant animals.

CERULOPLASMIN IN WILSON'S DISEASE. (E.)
Holtzman, N. A. (Johns Hopkins U. Sch.
Baltimore, Md.), M. A. Naughton,
F. L. Iber and B. M. Gaumnitz. J. Clin. Invest.
46(6):993-1002, 1967.

In a 31-yr.-old man with hepatolenticular degeneration, hepatic fibrosis and elevated liver and urinary Cu, the serum ceruloplasmin activity was normal (25 mg%) and crystallized serum ceruloplasmin showed no significant structural differences from that derived from normal controls. No abnormalities were detectable in terms of the tryptic peptide map, electrophoretic analysis or determinations of amino acid and sugar composition. Treatment with D-penicillamine (1 g/day) increased cupuresis from 400-4502 µg/24 hr. within 2 days; after 3.5 mo. of treatment, serum ceruloplasmin had fallen to 8 mg% and none was detectable 3 mo. later. The patient was sufficiently improved after 10 mo. of treatment to withdraw from therapy. Approx. 1 yr. later, when incipient recurrence of tremor occasioned another consultation, serum ceruloplasmin had reappeared, at a level of 4 mg%. Electrophoretic studies of partially purified serum ceruloplasmin from another patient with Wilson's disease, in whom the level was persistently low, were also entirely normal. Following an unspecified period of treatment, when penicillamine was withdrawn for 3.5 mo., serum ceruloplasmin rose from less than 2.0 to 6.5 mg% in the case of the second patient. It is concluded that the first patient's reaction to prolonged treatment with penicillamine may have resulted from a diminished sensitivity of the ceruloplasmin-synthesizing system to Cu.

8478 IDIOPATHIC RECURRENT CHOLESTASIS. (E.)
Stathers, G. (U. Sydney, Australia),
C. S. H. Reed and E. Hirst. Gastroenterology
52(3):536-543, 1967.

A 32-yr.-old woman is described who had obstructive jaundice at 19 yr., with further attacks at 27 and 31 yr. These attacks were marked by severe pruritus and lasted from 6-24 mo. Serum transaminases were markedly elevated. Laparotomy after the first attack showed a microscopically normal liver; there were no calculi in the common bile duct or gallbladder; some recent adhesions were noted around the gallbladder. Another laparotomy was performed after 8 yr., 2 mo. after a 10-day period of jaundice at the end of her first pregnancy; the common bile duct and gallbladder were opened and found to be empty and free from obstruction; the liver appeared cirrhotic and a liver biopsy was taken; there were some enlarged lymph nodes at the hilum of the liver, and some adhesions were present around the common duct; the pancreas, stomach, and duodenum were normal. Jaundice worsened after 2 days and hydrocortisone therapy was begun; after the immediate postoperative period, prednisone was begun at 60 mg daily; at discharge after 2 mo., prednisone was reduced to 30 mg daily; this was further reduced until a maintenance dose of 5 mg daily was reached after 5 mo.; this was discontinued after 4 mo.

Later liver biopsies were normal. The syndrome is preferably named "idiopathic recurrent cholestasis", and the features in this patient suggest an atypical recurring hepatitis.

8479 BILE DUCTULES IN CHOLESTASIS: MORPHOLOGIC EVIDENCE FOR SECRETION AND ABSORPTION IN MAN. (E.) Sasaki, H. (Mt. Sinai Sch. Med., New York, N. Y.), F. Schaffner and H. Popper. Lab. Invest. 16(1):84-95, 1967.

Both light and electron microscopy showed the presence of bile in the cytoplasm of ductular cells in biopsy samples derived from patients with extra- or intrahepatic cholestasis. Pinocytotic vesicles, also seen occasionally on the luminal cell surfaces in specimens from normal controls, were much increased in number and size and were found chiefly on the lateral and basal cell surfaces. Their presence on lateral surfaces was associated with separation of the basal halves of neighboring cells. Their presence on basal surfaces was associated with reduplication of the basement membrane and periductular fibrosis. These phenomena appeared to suggest that, in cholestasis, the movement of the vesicles was in a luminal-to-lateral and basal direction. Pinocytotic vacuoles were also found in the vicinity of and within multivesicular bodies in the supranuclear region, appearing to offer additional confirmation of the presence of an absorption process. Hyaloplasmic projections from the lateral surfaces appeared to indicate water transport across the cell membrane in this region, as did complex enfolding of basal cell surfaces and much increased interdigitation of lateral surfaces at the basal halves of the cells. Material with density similar to that of basement membrane was found in both basal and lateral intercellular spaces, apparently discharged from the epithelial cells by reverse pinocytosis and transported to an area close to the basement membrane, in whose reduplication it participated. There was no evidence of obstruction to the flow of bile through the ductules and no qualitative electron microscopic differences were found which could distinguish between intra- and extrahepatic cholestasis. In samples derived from patients with cirrhosis of the liver, without cholestasis, marked proliferation of ductular cells was in evidence, but enlarged pinocytotic vesicles were most numerous on luminal, as contrasted to basal or lateral, cell surfaces; the basal halves of lateral surfaces were interdigitated normally; basement membrane was not reduplicated and the ductules themselves were composed of flatter epithelium surrounding a narrower lumen. It is concluded that both secretion and absorption appear to take place in human bile ductules, with absorption increased significantly in the presence of cholestasis.

8480 ANTIGEN DELETIONS IN CARCINOGEN-INDUCED RAT HEPATOMATA. (E.) Baldwin, R. W. (U. Nottingham, England) and C. R. Barker. Nature (London) 214(5085):292-293, 1967.

Tumors were induced in inbred Wistar rats by continuous p.o. admin. of carcinogens. 4-Dimeth aminoazobenzene (0.06%) was fed in a low protein rice diet for 3 mo., followed by a basal ri diet for 2-3 mo.; 2-acetamidofluorene (0.04%) was admin. in a standard diet, and hepatoma developed regularly in males in 7-9 mo.; diethyl nitrosamine (1.5 mg daily) was admin. in drinkin water until tumors developed, after approx. 6 mo Primary tumors and normal rat livers were perfused in situ. Tumors were transplanted into isogeneic rats of the same sex as that of the primary host. Tissues were fractionated into soluble proteins (cell sap) and microsomes by ultracentrifugation; rabbits were immunized with normal rat liver fractions; immunodiffusion analyses were made in Petri dishes. Rabbit anti sera were exhaustively absorbed with normal rat serum before use. Protein contents of tissue fractions were normalized. Agar gel double diffusion analyses of soluble cell sap fractions fr 5 transplanted 4-dimethylaminoazobenzene-induced hepatomas showed that in every case 3 major norm liver antigens were deleted; these 3 were not detected in diethylnitrosamine tumors; 2 of 3 were deleted in 2-acetamidofluorene induced tumors. The qualitative nature of these alterations was confirmed by the use of agar gel plates into whi 2 mg/ml tumor cell sap was incorporated. Analys of deoxycholate solubilized tissue microsome fractions also revealed deletion of 3 of 5 detectable normal liver antigens in all 5 4-dimeth aminoazobenzene-induced hepatomas. Fewer normal liver antigens were deleted from primary tumors (although the quantities were lower than in normal liver) when compared with tumors which had been passaged for only a few generations. While individual tumors showed a varying pattern of ant gen deletion, there was a common group of antigen from which deletion occurred in the whole range of primary and transplanted tumors, irrespective of carcinogenic agent. The findings warrant further study of the influence of hepato-carcinogenic agents on the cell surface antigens of bot liver and induced tumors.

8481 OXYHEMOGLOBIN DISSOCIATION IN PATIENTS WITH HEPATIC ENCEPHALOPATHY. (E.) Zimmon, D. S. (Roy. Free Hosp., London). Gastroenterology 52(4):647-654, 1967.

The controls (Group 1, 7) consisted of 5 hospital patients without clinical, laboratory, or historical evidence of hepatic, cardiac, pulmonary disease and 2 studied while jaundiced as a result of extrahepatic biliary tract obstruction. Nine patients with cirrhosis were divided into 2 group according to the presence (Group 2, 4) or absence (Group 3, 5) of encephalopathy. Studies were made after an overnight fast and included pO_2, pCO_2, pH, whole blood O_2 content and capacity. When compared with the controls or with the norma curve of Severinghaus, Group 2 showed a slight, statistically insignificant right shift of the oxyhemoglobin dissociation curve (av. -0.64). Eleven determinations in Group 3 showed a

icant right shift (av. -3.26) when compared
mal controls or cirrhotic patients without
alopathy. These patients demonstrated the
atory alkalosis associated with hepatic
a or coma. There was no correlation between
gree of hypoxemia and the right shift of
ssociation curve. No abnormal hemoglobins
be demonstrated in Group 3. The correlation
isorder of oxyhemoglobin dissociation with
c encephalopathy suggests that the liver
e way maintains the functional integrity
oglobin and perhaps other respiratory pro-

STUDIES ON THE INTRACEREBRAL TOXICITY
OF AMMONIA. (E.) Schenker, S. (U.
Southwestern Med. Sch., Dallas), D. W.
less, E. Brophy and M. S. Lewis. J. Clin.
. 46(5):838-848, 1967.

major sources of intracerebral energy,
ine triphosphate (ATP), phosphocreatine,
ucose, as well as glycogen, were assayed in
cortex and base of rats given ammonium
e with resultant drowsiness at 5 min. and
uent coma lasting at least 30 min. Cortical
d phosphocreatine remained unaltered during
ion of coma. By contrast, basilar ATP,
lly 1.28 μmoles/g, was unchanged at 2.5 min.
ll by 28.1, 27.3, and 26.6% at 5, 15, and
. after ammonium acetate. At comparable
basilar phosphocreatine fell more strik-
by 62.2, 96, 77.1, and 71.6% from a control
of 1.02 μmoles/g. These basilar changes
not be induced by anesthesia, psychomotor
lation, or moderate hypoxia and were not due
creased accumulation of ammonia in the base.
se and glycogen conc. in both cortex and
fell significantly but comparably during
pment of stupor, and prevention of the
ral glucose decline by pretreatment with
se did not obviate ammonia-induced coma
e basilar ATP fall. These findings represent
irst direct evidence that toxic doses of
ia in vivo acutely affect cerebral energy
olism and that this effect is preferentially
ized to the base of the brain.

ACUTE HEPATIC COMA TREATED BY CROSS-
CIRCULATION OR EXCHANGE TRANSFUSION.
Burnell, J. M. (U. Washington Sch. Med.,
le), J. K. Dawborn, R. B. Epstein, R. A.
n, G. E. Leinbach, E. D. Thomas and W.
ler. New Eng. J. Med. 276(17):935-943, 1967.

cases of acute massive hepatic necrosis
severe coma are described: 3 patients were
ed by cross-circulation, 2 by exchange trans-
n. In the first case an exchange of a total
0 liters of blood with the patient's mother
factorily alleviated coma, but the patient
quently died of gastrointestinal hemorrhage.
e second, inefficient exchange of a total
liters of blood with a volunteer patient
carcinoma did not alleviate coma, and the
patient died. In the third, exchange of a total of 190 liters of blood, first with the patient's husband and then with her father, during 15 occasions over a 10-day period alleviated coma and allowed eventual complete recovery of the patient. The cross-circulation partners experienced a variety of reactions, but no late sequelae have been observed. In the fourth, exchange transfusion of 30 liters of blood during 5 days did not alleviate coma, and the patient died. A fifth case with viral hepatitis and coma was treated with 13 exchange transfusions over a 10-day period, with alleviation of coma, but the patient died of progressive hepatic disease. It was concluded that a judicious use of exchange transfusion of cross-circulation may prove advantageous in carrying patients through a period of hepatic coma when eventual recovery is expected.

INTERFERENCE WITH BILE PIGMENT UPTAKE IN THE LIVER BY FLAVASPIDIC ACID. (E.)

er, L. (U. California Med. Ctr., San
sco) and R. Schmid. *Gastroenterology* 53(1):
1967.

spidic acid, a phloroglucinol derivative
ned from male fern (*Dryopteris felix-mas*),
es unconjugated hyperbilirubinemia and
ased retention of BSP. The mechanism of
transient hepatic dysfunction was studied
le Sprague-Dawley rats (prepared with an
nal bile fistula) which were infused with
ubin (500 μg/ml), conjugated bilirubin
g/ml) or ^{3}H-mesobilirubinogen (444 μg/ml)
nstant rates of 1 ml/hr. for 10 consecutive
Approx. 6 hr. after beginning the infusions,
gle dose of neutralized aqueous flavaspidic
N-methylglucaminate (0.05 mmole/kg) was
i.v. There was abrupt, but transient,
ssion of biliary excretion of the 3 tetra-
les, concomitant elevation of their plasma
, and establishment of a new "steady-state"
patic pigment transfer characterized by
n of biliary excretory rates to preinj.
s at increased plasma conc. Since
spidic acid affects to a comparable extent
ic transport of tetrapyrroles that do or do
equire conjugation for biliary excretion,
redominant effect *in vivo* cannot be related
hibition of conjugation. In Gunn rats
miscible pigment pool had been labeled with
otopic tracer, flavaspidic acid displaced
of the intrahepatic bilirubin and released
to the circulation. A similar shift of
ubin from liver into plasma occurred in
rats, whose circulating pigment-binding
ity was acutely increased by infusion of
albumin. It is concluded that flavaspidic
affects hepatic transfer of bilirubin,
gated bilirubin and mesobilirubinogen by
ting for a shared mechanism of hepatic
e. The implications of this observation
he pathogenesis of human jaundice are
ssed in detail.

ANTIOXIDANT MAINTENANCE OF HEPATIC TRIGLYCERIDE SECRETORY ACTIVITY AND TIC FUNCTION IN CARBON TETRACHLORIDE POI- D RATS. (E.)

Crafton, C. G. (U. Tennessee
Units, Memphis) and N. R. DiLuzio. *Proc. Exp. Biol. Med.* 124(4):1321-1323, 1967.

Sprague-Dawley rats (125-225 g) were given
p. inj. of a corn oil suspension of the
oxidant, N,N'-diphenyl-p-phenylenediamine
mg/100 g). Controls received 2 inj. of an
valent vol. of corn oil. These inj. were
n 48 and 24 hr. before the p.o. admin. of
er undiluted CCl_4 or isotonic saline in a
of 0.25 ml/100 g. The animals were fasted
r. before p.o. intubation and received no
after treatment. Three hr. after CCl_4
n., Triton (p-iso-octyl polyoxyethylene phenol polymer) was admin. by tail vein in a dose of 50 mg/100 g as a 20% soln. (wt./vol.) in isotonic saline; controls received isovolumetric saline. In other experimental and control groups, the conc. of BSP in plasma was measured 10 min. after i.v. inj. of 50 mg BSP/kg body wt. The BSP was admin. 24 hr. after CCl_4. The prior admin. of the lipid antioxidant to rats which subsequently received CCl_4 p.o. prevented the CCl_4-induced depression of plasma triglyceride conc. and maintained a normal hepatic release of triglyceride into the plasma compartment, as assessed by the post-Triton hypertriglyceridemic response. Admin. of the antioxidant also prevented the CCl_4-induced impairment in the hepatic removal of BSP. These results, coupled with prior observation of inhibition of CCl_4-induced hepatic fatty infiltration, hepatic necrosis and lethality, indicate that antioxidants can modify the degree and nature of hepatic cell injury resulting from exposure to certain toxic substances.

8537 FINE STRUCTURE OF INTERPHASE LIVER CELL NUCLEI IN ACUTE ETHIONINE INTOXICATION.

(E.) Miyai, K. (U. Toronto, Ontario, Canada) and J. W. Steiner. *Lab. Invest.* 16(5):677-692, 1967.

A total of 87 white Wistar rats (46 males, 41 females) were divided into 4 groups. Group 1 received a synthetic diet consisting of casein (containing 3.5% methionine, so that methionine constituted 0.55% of the synthetic diet), 16.0%; corn oil, 5.0%; Jones Foster salt mixture, 4.0%; vitamin-sucrose mixture, 2.0%; and sucrose, 73%; the animals then received an i.p. inj. of 1 mg/g of 2.5% soln. of DL-ethionine in 0.9% saline. Group 2 received a regular diet consisting of Purina chow cubes, plus the same i.p. inj. of ethionine. Group 3 animals were fed the synthetic diet and some of them received an i.p. inj. of saline, while Group 4 animals received the regular diet, and some of them were given an i.p. inj. of saline. After sacrifice at various periods of time, liver sections from each group were studied under the light and electron microscope. Nuclear changes of rat liver cells in acute ethionine intoxication were observed from 15 min.-24 hr. after inj. In control groups, the nuclei of parenchymal cells were round or elliptical and measured 6.3-10.6 μ in diameter; approx. one-third of the hepatocytes were binucleated. The mean mitotic frequency in the parenchyma varied from 0.1-0.2%. No appreciable alteration in size or shape of nuclei occurred after admin. of ethionine; the proportion of binucleated cells and the mitotic frequency did not change. In both groups that received ethionine, the number of nucleoli per nuclear section tended to increase with progression of time, and this increase became statistically significant at the fourth hr. By electron microscopy, nucleoli showed progressive reduction in size, and dissociation and dispersal of their structural components. At later stages, the granular component of the nucleoli decreased, and ribosomes were fewer than normal in the cytoplasm and on the outer nuclear membrane. These observations suggest the presence of another mechanism, in addition to the inhibition of messenger RNA synthesis and a possible block in peptide chain initiation, by which protein synthesis is inhibited; ethionine may interfere with nucleolar function and thereby inhibit the synthesis of the precursors of ribosomes.

8538 PARTIAL HEPATECTOMY IN EXPERIMENTAL CARBON TETRACHLORIDE-INDUCED LIVER FIBROSIS. A HISTOLOGICAL AND BIOCHEMICAL STUDY IN RATS.

(E.) Olsson, R. (U. Goteborg, Sweden). Acta Chir. Scand. (Suppl. 366):3-85, 1966.

Liver fibrosis was induced in male rats by inj. of CCl_4 (0.1 ml/100 g body wt., admin. s.c. 3 times/wk.) for 4 mo. (Group 1), six mo. (Group 2) and 8 mo. (Group 3); in the latter 2 groups, inj. were given twice a wk. Biopsy sections obtained through laparotomy 1 wk. after CCl_4 was discontinued, showed that intoxication from 1 mo. of age during 8 mo. produced a liver fibrosis that was indistinguishable from that seen after 4 and 6 mo. of intoxication. Liver parenchyma displayed signs of liver cell degeneration as well as regeneration in all 3 groups. Liver hydroxyproline conc. was markedly elevated in all 3 groups. With minor exceptions, the DNA and RNA conc. were higher than normal in all 3 groups. A marked microscopic regression of fibrotic changes was seen in Groups 1 and 2 at 3 mo. and 3 wk., resp., after the intoxication procedure was discontinued. Regression consisted of a reduction in the thickness of trabeculae and in a decreased density of the trabecular network. In Group 3 signs of regression were uncommon 4 mo. and 3 wk. after cessation of the intoxication procedure. There was a reduction in the hydroxyproline conc. from biopsy to sacrifice in all 3 groups. Decreases noted in Groups 1 and 2 were dependent upon the initial conc. of hydroxyproline, the most pronounced reductions being observed in animals with the highest initial conc. of hydroxyproline. The decrease in Group 3 could not be correlated with a histological reduction in the relative amount of van Gieson-stained collagen fibers; this suggested the probability that the biochemical decrease in this group was a result of a decrease only in the alkali-soluble collagen. Fibrosis in Group 3 was considered irreversible, but that in Groups 1 and 2 was distinctly reversible. It was impossible to detect at biopsy any differences that could be used to predict reversibility or irreversibility of CCl_4 fibrosis. Transition to irreversibility was not reflected in hydroxyproline/DNA ratio, DNA conc., RNA conc. or RNA/DNA ratio in the biopsy specimens. Higher than normal liver wt. were encountered in all 3 groups. Pathologically elevated values of DNA and RNA conc. were found in Groups 1 and 3. Electrophoretic analysis of the serum proteins revealed low values for albumin, and inconstantly increased levels of α_1-, α_2-, and β_1-globulin. Removal of two-thirds of the fibrotic liver 3 wk. after discontinuance of th intoxication procedure was followed by a pronou proliferation of the liver remnant. In none of the groups was the liver wt. lower than normal mo. (Groups 1 and 2) and 4 mo. (Group 3) after surgery. Histologically, a decreased density o the trabecular network was usually observed mor frequently in the operated Group 2 and 3 animal than in the corresponding nonoperated animals. Defects in the trabecular network were commonly observed in animals from Groups 1 and 2. A decrease in hydroxyproline conc. was found in a groups of animals, but it was not always more pronounced than in the nonoperated animals. In all 3 groups, the reduction in hydroxyproline conc. was more pronounced at higher initial con of hydroxyproline, just as in the nonoperated Group 1 and 2 animals. The hydroxyproline conc at sacrifice was also consistently higher than normal in the operated animals. The abnormalit in liver RNA and DNA conc., observed in nonoper animals, were also encountered in partially hepatectomized rats. Hepatectomy was associate with an immediate mortality (day of operation a first postoperative day) of 7.6%; however, tota mortality did not exceed that in nonoperated animals. Partial hepatectomy did not influence serum protein abnormalities seen in the nonoper animals.

8539 SITE OF ACTION OF AFLATOXIN ON HUMAN LIVER CELLS IN CULTURE.

(E.) Zucker A. J. (London Sch. Hyg. and Trop. Med.), K. R. Rees, D. Inman and V. Petts. Nature (London) 214(5090):814-815, 1967.

Autoradiography investigations were made of the site of action of aflatoxin B_1 (from the Aspergi flavus-oryzae group) in human liver cells; titr tions of 3 aflatoxin fractions (purified crysta fractions B_1, G_1, G_2) were done. The fractions were dissolved in dimethyl formamide and dilute in 196 cultures of the liver cell growth medium Results showed that human embryo liver cells in culture incorporate uridine and thymidine, thus indicating that hepatic cells can synthesize RN and DNA. Low conc. of aflatoxin B_1 added to th cell culture inhibited nuclear RNA and DNA synt sis by the parenchymal cells. The authors conclude that the hepatotoxic action of aflatoxin on the human liver cell is similar to its actio on the rat liver cell, i.e., aflatoxin B_1 preve the production of messenger RNA, and perhaps prevents the RNA polymerase transcribing the DN molecule.

8540 SERUM PROTEIN AND CHOLINESTERASE CHAN IN ASSOCIATION WITH CONTRACEPTIVE PIL

(E.) Robertson, G. S. (Roy. Infirm., Aberdeen, Scotland). Lancet 1(7484):232-235, 1967.

In view of the similarity of metabolic effects between oral contraceptive therapy and pregnanc

ally involving liver damage, 4 oral prepara-
vere tested on 66 women between the ages of
44, divided into 2 groups: 33 women before
ll, at 1 mo. after starting treatment, and
o.; 33 women after taking the pill 12 mo.
ger. The pills were: Ovulen (ethynodiol,
nol), Ortho-Novin (norethisterone, mestranol),
trin (norethisterone, ethinylestradiol),
novlar 21 (norethisterone, ethinylestradiol).
cholinesterase level, serum-protein and
crit were determined. There was a general
rity of results in women under therapy for
with those under it for 1 yr. or longer.
gh the results do not indicate clinically
icant changes in liver function, there were
tions of a steroid-induced depression of
ver's ability to synthesize protein or to
e it into the circulation (which might be
reted as a stage before hepatocellular
).

SOME EFFECTS OF CHRONIC ETHANOL FEEDING ON VITAMIN B_6 DEFICIENCY IN THE RAT.

French, S. W. (San Francisco Gen. Hosp.,
) and J. Castagna. Lab. Invest. 16(4):526-
967.

c ethanol feeding worsened the deleterious
s of vitamin B_6 deficiency in rats by
sing the survival rate, increasing the
nce of acrodynia, and developing a fatty,
t a cirrhotic, liver. Possibly a longer
re to the dietary regimen is necessary for
velopment of cirrhosis, or the rat may not
vulnerable to vitamin B_6 as other species.
hydroxyphenylalanine decarboxylase activity
uced by ethanol activity; the activity of
nzyme was restored to near control levels
ition of pyridoxal-5-phosphate to the assay
This indicates that ethanol decreased the
activity by decreasing the conversion of
xine into the active coenzyme (pyridoxal-
phate) rather than by affecting the level
apoenzyme. The activity of glutamic-
c transaminase, a pyridoxal-phosphate
ent enzyme, was not influenced by ethanol
ion when the rats were fed diets supplemented
arious doses of pyridoxine chloride, which
tes that ethanol did not increase the
n B_6 requirements. Ethanol affects vitamin
abolism by nonspecific means which are yet
elucidated.

EVALUATION OF THE THERAPEUTIC ACTION OF PROTECTIVE SUBSTANCES ON THE LIVER.

Issekutz, L. (Med. U. Budapest).
mittelforschung 17(4):419-424, 1967.

od, devised to test compounds for protective
ty against hepatotoxic effects, is described.
160-180 g) of the same stock were 60%
ctomized and then exposed to a specific
of CCl_4 in the air breathed. Some were
d with the presumptive protective substance;
ls were given sham treatment. The amount
of protection is measured in terms of increased regeneration due to the inhibition of CCl_4 effects. To make the measurement, it is necessary to have a reliable index of regeneration. The usual value, g of regenerated liver tissue/100 g of body wt. at 10 or 21 days cannot be used: Increase in body wt. is almost completely inhibited by CCl_4 whereas, liver regeneration, although slower than normal, still proceeds; regeneration in CCl_4-treated animals seems to be more rapid than it actually is. The total liver is weighed when the animal is killed; the lobes removed at partial hepatectomy are weighed at that time. It is possible to calculate the residual liver at hepatectomy by the method of Brues et al. The degree of regeneration, expressed in per cent, is equal to g of regenerated liver tissue x 100 divided by the g of the excised lobes. Regenerated liver tissue is equal to liver wt. at death minus residual wt. Regeneration is slow at first but gathers momentum and is (for 60% hepatectomy) virtually complete in 21 days in normal untreated animals of medium wt. The degree of regeneration in per cent at 21 days in the controls was 98 (av. of 15 rats) and 83 (av. of 30 rats) for those treated with CCl_4. The BSP retention showed significant differences between the untreated and CCl_4-treated animals; these differences generally occurred throughout the 3-wk. period; the most marked difference was on day 21; the av. dye retention in CCl_4-treated animals (30) was 32.6%; the av. retention in untreated animals (15) was 2.7%. The degree of regeneration was increased and the dye retention decreased by liver protective compounds such as Ripason (a liver extract) in CCl_4-treated animals. Using the degree of regeneration, BSP retention and a number of other factors easily obtained, a formula was constructed which sharply reflects changes in the liver function of experimental animals. To obviate confusion, percentages are used as simple numbers. Degree of regeneration is used as 89 not 89%; if all animals survive in a group the figure used is 100 not 100%; if half survive the number is 50. The numerical value obtained from the formula is called the "regenerative value" (RV) by the author. This is the product of the degree of regeneration (say 89), the percentage of animals having normal liver function (BSP retention less than 5%) (say all, 100) and the percentage of animals still alive (say all, 100) divided by the av. percentage of dye retention by the group, (say 4) multiplied by 100. RV equals 89 x 100 x 100 divided by 4 x 100 equals 8900 divided by 4 = 2225. If the degree of regeneration is 83; half the animals have normal liver function, 50; all animals alive, 100; av. dye retention, 10; then RV equals 83 x 50 x 100 divided by 10 x 100 = 415. The highest possible value is about 3703.

8543 NEW STUDIES ON THE PREVENTION AND CURE OF EXPERIMENTAL HEPATIC DYSFUNCTION.

(E.) Rohn, S. (Solco Ltd., Basel, Switzerland), M. Kiraly and S. Neukomm. Arzneimittelforschung 17(1):47-49, 1967.

The controlled damage of mammalian liver by CCl_4 dosage to provide models upon which to test antitoxic properties of experimental drugs, leads to functional impairment in both animals and human liver. This causes biochemical changes, detectable by biopsy, or examination of blood or bile. Fifteen female rabbits (3 batches of 5 animals each), 30 female rats (3 batches of 10), and 48 mixed rats (3 batches of 10 females and 3 batches of 6 males) were subjected to CCl_4 damage. Specific liver tests (BSP, and electrophoresis determination of serum proteins) were done on these animals. Results showed that female rats are more resistant to CCl_4 than males, especially as seen in a less marked change in BSP retention and in albumin synthesis. β-Globulin increased in both sexes, but γ-globulin showed little change. The chronologic and quantitative changes observed occurred in the order: BSP > β-globulins > albumin. Liver extralyzate (aqueous extract plus hydrolyzate of mammalian liver containing neither anti-anemic principle nor proteins) normalizes BSP elimination and reduces serum protein changes; normalization was directly proportional to functional impairment.

8544 THE TOXICITY OF AJMALIN IN RATS WITH LIVER DAMAGE.

(Ger.) Sándor, P. (Med. U. Budapest), K. Szentágothai and A. G. B. Kovách. *Arzneimittelforschung* 17(5):618-619, 1967.

The LD_{50} (i.v.) for ajmalin, one of the Rauwolfia alkaloids, was determined using rats (150-200 g). With the thought that LD_{50} might be reduced among patients with liver damage, white rats were given 0.2 ml/kg of CCl_4 and paraffin oil mixed in equal quantities in one dose. Histological examination 24 hr. after receiving CCl_4 showed fatty infiltration and necrotic centers in the livers of the rats. Death rate was established at LD_{50} for rats with damaged livers. LD_{50} for normal rats was 30 mg/kg; at this dosage 66% of the rats with damaged livers were dead; these figures are significant. The presence of liver damage increased the lethality of ajmalin 15-16% on the basis of the number of animals in the test. The percentage of survivals was 30-32% greater among the animals without liver damage.

8545 THE PREVENTION OF FATTY LIVER BY ADMINISTRATION OF ADENOSINE TRIPHOSPHATE.

(E.) Hyams, D. E. (Harvard Med. Sch., Boston, Mass.), E. B. Taft, G. D. Drummey and K. J. Isselbacher. *Lab. Invest.* 16(4):604-615, 1967.

Three hepatotoxic agents, ethionine, the antibiotic azaserine and CCl_4, were admin. to female rats to study their effects on the liver. The 3 drugs produced a fatty liver associated with a rise in plasma free fatty acids, fall in ATP conc., inhibition of protein synthesis and decrease in lipoprotein synthesis. The ATP-depleting effect of ethionine was due to formation of S-adenosylethionine from ethionine and ATP; S-adenosylethionine accumulates in the liver, its production serves to trap the adenosine moiety of ATP and the ATP levels fall. ATP parenteral admin. after ethionine admin. had as a result the reversal of changes in both protein synthes and fat content of the liver. In cases of CCl_4 and azaserine, ATP inj. failed to decrease prot synthesis inhibition but fat accumulation in th liver was reduced or prevented. These agents produce a fatty liver by a mechanism not solely dependent on protein synthesis; hepatic protein synthesis may be inhibited despite adequate ATP conc. in the liver. ATP admin. causes a suppre sion of free fatty acids, which increase with admin. of the 3 hepatotoxic agents, thus preven ing hepatic lipid accumulation. This may be th main mechanism by which ATP prevents fatty live development.

8546 LIVER PARENCHYMAL CELL INJURY. V. RELATIONSHIPS BETWEEN PATTERNS OF CHLOROMETHANE-C^{14} INCORPORATION INTO CONSTITUEN OF LIVER *IN VIVO* AND CELLULAR INJURY.

(E.) Reynolds, E. S. (Peter Bent Brigham Hosp., Bost Mass.) and A. G. Yee. *Lab. Invest.* 16(4):591-6 1967.

Studies of the hepatotoxic effects of members o the chloromethane series on young male rats reveal that CCl_4 causes early centrilobular suppression of hepatic glucose-6-phosphatase ar transient intracellular Ca influx which is associated with centrilobular necrosis. Degra tion of the endoplasmic reticulum 2 hr. after the rats were fed 830-2600 μM chloromethane/10 g body wt. occurred, resulting in the doubling of the cell sap RNA content in the liver. This is due to the preferential incorporation of CCl_4 and chloroform into the lipid and protein constituents of the endoplasmic reticulum, the ability of these agents to disrupt the ribosome membrane of the granular endoplasmic reticulum and to cause eventual centrilobular necrosis (at 24 hr.). Reaction of chlorocarbon cleavage products of CCl_4 and chloroform with sulfhydryl groups of cysteine and homocysteine suggests th this may be one of the primary mechanisms of their hepatotoxic action. ^{14}C-Label from both CCl_4 and chloroform is recovered in an amino ac locus corresponding to methionine, while protei bound ^{14}C from dichloromethane, methylchloride and formaldehyde occurs at a locus correspondin to serine; bicarbonate-C fails to label those constitutents of the liver lipids and proteins labeled by the chloromethane carbon. The hypot sis that the relative chloroform and CCl_4 hepatotoxicity is due in part to the attack by their cleavage products on the granular endopla reticulum is supported by the shift in labeling patterns of the ribosomes and other chemical constituents of the cells, as lipids and amino acids, with increasing chloromethane chlorine content.

ioguardi and A. Agostoni. *Klin. Wschr.* 45(1):
8, 1967.

n liver tissue was obtained during hepatic
gery and also by biopsy. Blood serum was
en from groups of fasting patients: (a) normal
jects, (b) patients with acute viral hepatitis
tages of onset and early illness, and (c)
ents with definite precoma or hepatic coma
owing acute hepatitis. After thorough washing
iver tissue with saline to remove RBC, and
genization, it was alternately frozen and
wed 3 times to break down the cells; the
pension was then treated 3 times with ultra-
nd at 20,000 Herz. After centrifuging, the
rnatant was dialyzed against 0.005 M buffer
H. 7.5. Serum was also dialyzed against the
type of buffer. Separation of the enzymes
first done on Sephadex columns and then by
trophoresis. Testing the separated enzymes
buffered substrates in the presence of malic
drogenase revealed the presence of 2 glutamic-
acetic transaminases in human liver tissue, one
rated from the cytoplasmic space, the other
ved from the mitochondria; the glutamic-
acetic transaminase from the mitochondria had
vity peaks at pH 6.0 and 7.6; the enzyme of
cytoplasmic space showed peak activity only
H 7.6. Electrophoresis caused the mitochondrial
me to migrate toward the anode and the cyto-
mic one toward the cathode. Normal serum has
low conc. of these enzymes that even chromatog-
hy or electrophoresis cannot accurately deter-
them. During virus hepatitis the serum levels
he enzymes increase to correspond to the liver
els of the 2 transaminases. In the course of
ssion the mitochondrial enzyme decreases more
dly than the cytoplasmic. In the beginning
ges of a liver coma after acute hepatitis both
saminases are present in serum; the mitochon-
al GOT is especially high. Ten days after a
episode, the mitochondrial enzyme had fallen
ne-third the cytoplasmic. The differential
ermination of these isoenzymes might serve as
seful index of the severity of viral hepatitis.

4 A SERUM ANTIGEN (AUSTRALIA ANTIGEN) IN
DOWN'S SYNDROME, LEUKEMIA, AND HEPATITIS.
) Blumberg, B. S. (Inst. Cancer Res.,
ladelphia, Pa.), B. J. S. Gerstley, D. A.
gerford, W. T. London and A. I. Sutnick. *Ann.
ern. Med.* 66(5):924-931, 1967.

od specimens from 84 patients (79 males, 5
ales) with Down's syndrome and from a control
up of 76 males with epilepsy were studied, as
l as those from 82 patients with polycythemia
a and others with other diseases, for the
sence or absence of Australia antigen (Au(1)).
omosome studies were performed on 17 patients
with Down's syndrome and 4 controls. Of 84 with Down's syndrome, 25 (29.8%) had detectable Australia antigen in their serum; this was the highest frequency found in any patient group so far tested. Four of 76 controls had Australia antigen. Five (10.4%) of 48 sera from patients suspected of having viral hepatitis were found to have Australia antigen. In addition, 1 of 2 patients with Fanconi's anemia and 1 of 12 with Hodgkin's disease had the antigen. Fourteen of 17 patients with Down's syndrome on whom chromosome studies were done were found to be trisomic for chromsome 21, the classical finding in this disease. Down's syndrome patients with Australia antigen had, on the av., a higher level of vitamin B_{12} than did those patients without this trait. Several hypotheses are discussed as an attempt to explain the various associations of Australia antigen with several disease states. Discovery of the frequent occurrence of Australia antigen in patients with viral hepatitis suggests the possibility that the agent present in some cases of this disease may be Australia antigen or be responsible for its presence.

8585 INFECTIOUS HEPATITIS. EVIDENCE FOR TWO DISTINCTIVE CLINICAL, EPIDEMIOLOGICAL, AND IMMUNOLOGICAL TYPES OF INFECTION. (E.) Krugman, S. (New York U. Sch. Med., N. Y.), J. P. Giles and J. Hammond. *J.A.M.A.* 200(5):365-373, 1967.

Serum from patients with infectious hepatitis was admin. p.o. (0.5-1.0 ml) or i.m. (0.10-0.25 ml) to noninfected subjects in 7 trials involving 54 institutionalized, mentally-retarded children, aged 3-10 yr., leading to identification of 2 distinctive forms of the disorder. Trial A involved 11 new admissions, treated p.o. with pooled serum from 27 patients; 10 of 11 infected. Trial B involved the 10 infected during Trial A, all of whom were treated i.m. from the same serum pool, 6 mo. later; 6 of 10 infected. Trial C involved 14 new admissions, 8 of 14 treated i.m. with serum from patients with Type I hepatitis and 6 of 14 kept in close contact with the treated subjects; 14 of 14 infected. Trial D involved 14 new admissions, 9 of 14 treated i.m. with serum from patients with Type II hepatitis and 5 of 14 kept in close contact with the treated subjects; 12 of 14 infected. Trial E involved 9 new admissions, 6 of 9 treated p.o. with serum from a patient with Type II hepatitis + γ-globulin (0.01 ml/lb., i.m.) and 3 of 9 kept in close contact, as above; 5 of 9 (all treated subjects) infected. Trial F involved 6 new admissions, all treated p.o. with serum from patients with Type II hepatitis, but without γ-globulin; 5 of 6 infected. Type I hepatitis resembled the classical picture of infectious hepatitis, characterized by a 31-42 (mean = 37) day incubation period, a 3-19 day period of abnormal serum transaminase activity, consistently abnormal thymol turbidity and a high degree of contagion.

Type II resembled the classical picture of serum hepatitis, with a 55-90 (mean = 71) day incubation period, a 35-155 day period of abnormal serum transaminase activity, normal thymol turbidity test. Type II was moderately contagious, and definitely infective p.o. As concerned Trials A and B, a careful comparison of incubation periods, thymol turbidity test results, etc., confirmed other evidence that homologous immunity followed infection with either Type I or Type II, with no evidence of the development of heterologous immunity, in either case.

8586 EFFECT ON THE INFECTIVITY OF VARIOUS VIRUSES BY THE INTESTINAL FACTOR OF NORMAL MICE WHICH INACTIVATES MURINE HEPATITIS VIRUS. (E.) Piazza, M. (U. Naples, Italy), G. Pane, L. Picciotto and D. Lombardi. Nature (London) 213(5073):293-294, 1967.

A method is described for the preparation of the factor, in the first section of mucosa of small intestine of adult mouse, which inactivates murine hepatitis virus (MHV-3). Small intestine of 30 g, 3-mo.-old mice was homogenized in 3 vol. of buffered saline, centrifuged at 30,000 times gravity for 1 hr. at 4° C and the sediment discarded; the supernatant was saturated with ammonium sulfate, the precipitate collected by centrifugation and dissolved in a minimal vol. of distilled water. The supernatant was dialyzed against 70% ammonium sulfate and the precipitate collected by centrifugation, dissolved in a minimal vol. of 0.05 M tris (2-amino-2-hydroxymethyl-1,3-propanediol)-HCl buffer pH 7.4, and dialyzed against this buffer. The partially purified factor was titrated: progressive dilutions of inhibitor (2 ml) were incubated for 2 hr. at 37° C in a water bath with an equal vol. of a suspension of MHV-3 containing 10^6 LD_{50}/0.1 ml. Groups of ten 4-wk.-old Swiss mice were inj. i.p. (0.2 ml) with each sample and the mortality recorded. One inhibitor U was the amount contained in the highest dilution which neutralized 10^6 LD_{50} MHV-3. Activity of inhibitor fraction on infectivity of various viruses was measured. A weak inhibitory effect was observed on the infectivity of influenza, measles, infectious bronchitis of chicken, coxsackie A-9, SV-40 and variola viruses. With the exception of rubella virus, the inhibitory effect seemed to be highly specific for murine hepatitis virus. No effect on the hemagglutinating activity of influenza and measles virus was observed when 1 U of inhibitor was tested against 4 hemagglutinating U of the resp. virus.

8587 THE EFFECT OF CORTICOSTEROIDS ON SERUM ASPARTIC AND ALANINE AMINOTRANSFERASES IN VIRAL HEPATITIS. (Pol.) Wysocki, J. (Inst. Infect. Dis., Acad. Med., Warsaw, Poland). Pol. Tyg. Lek. 21(49):1880-1882, 1966.

Aspartic aminotransferase activity and that of alanine aminotransferase was assessed in the sera of cortisone-treated (30 mg/day; 182 and 229 patients, resp., for each enzyme) and vitamin-treated (182 and 235, resp.) patients with viral hepatitis; the latter served as controls. Patier were subdivided according to age (4-18 yr., 19-60 yr. and over 60 yr.) and disease severity (slight 6 mg% or less of bilirubin, moderately severe, 6-12 mg%, and severe, more than 12 mg% of bilirubin). The corticosteroid treatment did not have any pronounced effect on the activity of these 2 serum enzymes.

8588 THE EFFECT OF CORTICOSTEROIDS ON SERUM ALDOLASE ACTIVITY IN VIRAL HEPATITIS. (Pol.) Wysocki, J. (Inst. Infect. Dis., Acad. Med., Warsaw, Poland). Pol. Tyg. Lek. 21(50): 1917-1919, 1966.

Serum aldolase was studied in 110 patients with viral hepatitis who were treated with cortisone (30 mg/day) and in 173 control patients who were treated with vitamins. Patients were subdivided according to age (4-18 yr., 19-60 yr., and more than 60 yr.) and severity of the disease (6 mg% of bilirubin or less, 6-1 mg% bilirubin and more than 12 mg% of bilirubin). In the doses used, the corticosteroids had no pronounced effect on serum aldolase activity in the patients with viral hepatitis.

8614 PLATELET AGGREGATION IN PATIENTS WITH LAENNEC'S CIRRHOSIS OF THE LIVER. (E.) Thomas, D. P. (Lemuel Shattuck Hosp., Boston, Mass.), V. J. Ream and R. K. Stuart. New Eng. J. Med. 276(24):1344-1348, 1967.

Platelet aggregation in response to adenosine diphosphate and thrombin was compared in normal subjects and in 20 patients with advanced Laennec's cirrhosis of the liver. In 9 cirrhotic patients with prolonged thrombin times and normal fibrinogen levels, platelet aggregation was significantly delayed in response to both adenosine diphosphate and thrombin, as compared to normal subjects. Plasma from an additional 6 patients with prolonged thrombin times, who were thrombocytopenic, delayed aggregation of platelets from normal subjects. It is suggested that circulating fibrinogen breakdown products, resulting from excessive fibrinolysis, are responsible for this impaired platelet aggregation in some cirrhotic patients. These findings indicate an additional cause for defective hemostasis in patients with cirrhosis of the liver.

8615 THE BLOOD VOLUME IN POST-NECROTIC CIRRHOSIS OF THE LIVER WITH SPLENOMEGALY. (E.) McFadzean, A. J. S. (U. Hong Kong) and D. Todd. Clin. Sci. 32(3):339-350, 1967.

In 30 patients with postnecrotic cirrhosis of the liver associated with varying degrees of splenomegaly, the RBC mass and plasma vol. were measured, resp., by ^{51}Cr-tagged RBC and Evans' Blue (T-1824). None had a reduced RBC mass; a low venous hematocrit, present in the majority of patients, was due to an increased plasma vol. In those with more than a minor degree of splenomegaly the body hematocrit:venous hematocrit ratio was raised, with 1 exception, to unity or above; the rise was proportional to the degree of splenomegaly. After splenectomy, the ratio fell to normal. The mixing curves of ^{51}Cr-tagged RBC within the spleen (in all but 1 of those with elevation of the body hematocrit:venous hematocrit ratio) had 2 components, 1 fast and the other slow. It was thought that a pool of blood of high hematocrit value within the spleen was responsible for the elevation of the body hematocrit:venous hematocrit ratio above the normal range. Fourteen patients, 10 of whom had body hematocrit:venous hematocrit ratios of unity or above, were restudied 2 yr. after splenectomy and the ratio in each was found to be below unity. An expanded plasma vol., present before operation in all but 2 of the 14 patients studied, persisted after splenectomy. In 5 it was reduced, but in 4 it had expanded further. An expansion of the RBC mass encountered in a number of patients after splenectomy was attributed to correction of hemolysis.

8616 ELECTROLYTE EXCRETION DURING THE SPONTANEOUS RECOVERY FROM THE ASCITIC PHASE OF CIRRHOSIS OF THE LIVER. (E.) Pecikyan, R. (Goldwater Mem. Hosp., Welfare Island, N. Y.), G. Kanzaki and E. Y. Berger. Amer. J. Med. 42(3):359-367, 1967.

Five patients are described who recovered from the edematous state of cirrhosis of the liver while on a liberal salt intake, without the use of diuretics. They received ordinary ward diets containing 50-150 mEq Na daily. Urine was collected daily, its vol. measured, and its Na and K content analyzed. The rate of natriuresis was calculated graphically. Ascites had been present for 4-11 mo., and the patients had required 4-14 paracenteses. Natriuresis began 1 mo. before recovery was clinically evident. The urinary Na excretion increased from less than 1 mEq to over 100 mEq daily. The rate of increase was striking constant, Na excretion doubling every 2.2-3.0 day During the 21-day period of natriureses, water excretion did not always increase. In 3, the correlation between the urine vol. and the day of the natriuretic period was not significant; in the other 2, the coefficients were significant, and the urinary vol. increased at a rate of 37 an 18 ml daily, resp. K excretion measured in 4 patients did not change during the natriuretic period. Urinary Na, water, and K excretion increased in the postnatriuretic period as compared to the prenatriuretic period. Following natriuresis, there was a small increase in the RBC count, hemoglobin conc., and serum albumin conc.; there was some decrease in WBC count, bilirubin conc., and BSP retention. Once the natriuresis was completed, ascites did not recur over a subsequent observation period of 3-7.5 yr., except in

8617 SERUM AND LYMPH LIPIDS IN RABBITS WITH CARBON TETRACHLORIDE-INDUCED CIRRHOSIS OF THE LIVER. (E.) Kotani, M. (U. Kyoto Med. Sch., Japan), K. Seiki, A. Yamashita, A. Takashima, T. Nakagawa and I. Horii. J. Lipid Res. 8(3):181-186, 1967.

Lymph flow and the composition of lymph lipids from the hepatic and thoracic ducts of rabbits with cirrhosis of the liver (induced by 46-51 i.m inj. of a mixture of CCl_4 and olive oil at 4-day intervals) are compared with those of control animals inj. with olive oil only. In cirrhotic animals, the conc. of lymph lipids was not greatl altered, but lymph flow (and consequently the hourly transport of lipids by lymph) was greatly increased; the increase in transport of cholester esters, free cholesterol, and phospholipids by way of the thoracic and hepatic duct lymph was particularly striking. The conc. of these lipid fractions in serum from the cirrhotic rabbits was also increased. The differences normally observed between lipid fatty acid compositions of serum and lymph disappeared in cirrhotic animals; this is interpreted as due to increased hepatic permeability to lipoproteins.

MACROGLOBULINS IN CHRONIC PANCREATITIS
AND LIVER CIRRHOSIS. COMPARISON WITH
JMATOID FACTOR MACROGLOBULIN. (E.)
N. (King Gustaf V Res. Inst., Stockholm)
Hedman. J.A.M.A. 200(11):951-960, 1967.

tation constants and hemagglutination titers
termined for serum samples derived from 10
s with chronic pancreatitis and 8 with
is of the liver, and samples were also
ed to cold precipitation, zone electro-
c and immunoelectrophoretic studies for
pose of comparing macroglobulins with the
oid factor macroglobulin, γM, whose sed-
ion constant lies between 18.2-18.8
g U. Pronounced macroglobulinemia (with
o to 13.6%) was found in patients with
pancreatitis, due primarily to an increase
acroglobulin, with γM increased to a much
degree or not at all. In patients with
is of the liver, a pronounced gammaglob-
a (with conc. up to 40.3%) was due pri-
to increase of a γ-globulin (γG) whose
tation constant was 6.5-7.0 Svedberg U,
eumatoid factor γM increased to a consider-
sser degree. It is concluded that the
positive sheep cell tests sometimes obtained
ents with chronic pancreatitis or cirrhosis
liver may be due to these secondary or in-
ent, relatively moderate increases of γM,
he macroglobulins which are increased most
cantly, in these disorders, belong to es-
ly different groups.

THE PASSAGE OF CEPHALOTHIN INTO AND
OUT OF ASCITIC FLUID. (E.) Wilson,
Tufts U. Sch. Med., Boston, Mass.), T. C.
s and M. A. Madoff. Amer. J. Med. Sci.
449-452, 1967.

ement of cephalothin (7-(thiophene-2-
do) cephalosporanic acid) into and out of
toneal cavity of 11 cirrhotic patients
cites was studied. Only 2 patients had
holic cirrhosis. Cephalothin, in 1-g
was admin. i.v. or i.p. in the course of
tic or therapeutic paracenteses. Blood
tic fluid were collected every hr. for
fter i.v. admin.; after i.p. admin., blood
d were collected at 1/2, 1, 2, 4, 6, 9,
24 hr. In both groups, urine was col-
for 24 hr. Antibiotic activity was de-
d by the cup-plate dilution method with
lutea, and 2-fold serial dilution with
ococcus 209-P. Results showed that i.v.
gave higher serum levels at 1 hr. than did
nin., but there was no difference in anti-
levels at 2 and 4 hr., although i.p. admin.
measurable serum activity for a longer
of time. After i.v. admin., approx. 77%
total drug was recovered from the urine
the first 24 hr., with 67% excreted during
st 6 hr. After i.p. admin., 55% was ex-
in 24 hr., with 28% after the first 6 hr.
pain, side reactions, or liver or renal
n changes were noted.

8620 THE RELATION OF CIRRHOSIS OF THE LIVER TO RENAL HYPERTENSION. A REVIEW OF 639 AUTOPSIED CASES. (E.) Schwartz, D. T. (Columbia-Presbyterian Med. Ctr., New York, N. Y.). Ann. Intern. Med. 66(5):862-869, 1967.

Among 14,448 autopsies performed at St. Luke's Hospital from 1950-1964, and at Columbia-Presbyterian Medical Center from 1932-1964, inclusive, there were 675 cases of liver cirrhosis: 435 (66.6%) had Laennec's cirrhosis, 100 (15.3%) had postnecrotic cirrhosis and 75 (11.4%) had biliary cirrhosis. An associated hepatoma was found in 44 cases. Complete analysis of 639 case records revealed that 381 (59%) had esophageal varices. The incidence of diastolic arterial hypertension was 8%, while an additional 5% had a history of hypertension that disappeared with the development of cirrhosis. The course of arterial blood pressure differed according to the presence or absence of renal disease. Among those cases without renal disease, arterial hypertension was rare and was not altered by the development of cirrhosis. Among those with renal disease, sustained arterial hypertension was reversed with development of appreciable portal-systemic shunting, as evidenced by demonstrable esophageal varices, but was not reversed in the absence of varices. The disappearance of hypertension was not related to the serum albumin:globulin ratio or to the development of ascites. Protection against arterial hypertension in those with renal disease who developed varices was lost when an end-to-side portacaval shunt was made. The mechanism of this protection against hypertension is unknown, but it is suggested that portal venous blood contains a substance which inhibits the synthesis of hepatic angiotensinase and that this substance is diverted from the liver in subjects with esophageal varices. The reversal of flow in the portal vein is thought to be necessary for this process, and it is suggested that end-to-side portacaval shunt involves some risk of leading to arterial hypertension in the treatment of patients with known renal disease.

OF THE BILIARY TRACT. (E.) Glenn, F.
rk Hosp.-Cornell Med. Ctr., New York,
Surg. Gynec. Obstet. 124(5):974-988, 1967.

a 33-yr. period, 1078 patients were sub-
to common duct exploration in search of
. During this same period, a total of
tients were operated upon for nonmalignant
of the biliary tract. Of 4677 who were
d upon for nonacute cholecystitis, usually
ted with gallstones, 694 (15%) were also
ed to common duct exploration in search of
; calculi were removed from 416 (8.8%).
tality rate for those who underwent ex-
on combined with cholecystectomy was 4.3%.
ority of patients explored (428) and the
y of those who had calculi removed (276)
yr. of age and older. The mortality rate
se 50 yr. of age and older was 6.1%, com-
o a 1.5% mortality rate for those under
During the same period, 172 patients of
erated upon for acute cholecystitis were
ed to common duct exploration; calculi
noved in 101, an incidence of 7.5%. The
ty rate for those undergoing cholecystectomy
ledochotomy was 5.4%. There were 212
s upon whom choledochotomy was performed
condary procedure for the manifestations
on duct obstruction associated with calculi.
were removed in 154 (72%); mortality rate
%.

EXPLORATION OF THE COMMON BILE DUCT WITH
VAN BUREN SOUNDS. (E.) Meyerowitz,
lbert Einstein Sch. Med., Bronx, N. Y.).
Surg. 113(6):861, 1967.

Buren urethral sound is said to be widely
Great Britain for exploration of the
ile duct and is also said to be more ad-
us for this purpose than the Bakes'
which is employed in the United States.
Buren sound offers the surgeon a better
gives him better control of the instru-
t is also in contact with the full length
uct at one and the same time, whereas the
ilator can contact only one segment at a
n addition to use of the sound as an
ory instrument, it is said to simplify
denal sphincterotomy by allowing the
to cut down on it while it is held firmly
with its tip protruding through the
of Vater.

EXPOSURE OF INTRAHEPATIC BILE DUCTS
THROUGH INTERLOBAR FISSURE. (E.)
W. R. (U. Colorado Med. Sch., Denver).
nec. Obstet. 124(3):491-500, 1967.

ients with various forms of bile duct
(severe cholestasis, biliary cirrhosis,
titis, jaundice, portal hypertension)
are described in whom the major intrahepatic bile ducts were exposed by separation of the lobes of the liver through the avascular interlobar plane. In each there was no other method of access to intrahepatic ducts for correction of stenotic lesions or anastomosis to the intestine. This simple, straightforward anatomic approach allows exposure and accurate anastomosis between either the proximal portion of the common duct or the major radicles and the intestine, or the distal common duct remnant. A Roux-en-Y of jejunum was utilized in 2 of 3 patients requiring replacement of the common duct, and the duodenum was used in the third. In 1 patient, no part of the common bile duct could be found and only a temporary external biliary fistula was formed; subsequently, an internal fistulous connection between the liver and the duodenum developed spontaneously which allowed him to live fairly well for 9 subsequent yr. despite the development of advanced biliary cirrhosis. In one patient, a collar of heavy fibrous tissue surrounded the common bile duct inside the liver, and the direct approach which has been described facilitated surgical management of his condition. In the 11-yr.-old boy, a technically difficult situation accrued from a gunshot wound, previous operations, advanced biliary cirrhosis and portal hypertension; in spite of all of this, the intrahepatic main bile ducts were exposed and anastomosed to the duodenum by way of separation of the lobes of the liver through the avascular interlobar plane. It is concluded that the procedure described is merely application of anatomy to the soln. of difficult and unusual problems occasionally encountered in biliary tract surgery.

8631 JIRGL'S REACTION AND WUANI'S (LATEX) TEST IN THE DIFFERENTIAL DIAGNOSIS OF JAUNDICE. (Sp.) Ferreira, E. B. (Fac. Med., Porto Alegre, Brazil). Prensa Med. Argent. 53(36):1943-1950, 1966.

The Jirgl and Wuani tests were each performed on 20 jaundiced patients. A positive Jirgl reaction was found in 11 cases (6 with cholestasis and 5 with complete obstruction). A negative Jirgl reaction was noted in 9 cases (1 hemolytic jaundice, 7 hepatocellular and 1 obstructive). A positive Wuani (latex) occurred in 8 cases (5 hepatocellular, 1 cholangiolitic and 2 complete obstruction). A negative Wuani test was found in 12 cases (1 hemolytic, 2 hepatocellular, 1 intrahepatic cholestasis, 4 extrahepatic and 4 complete obstruction). Sixty healthy subjects and 60 nonjaundiced patients with various disorders were tested. The percentage of positive Jirgl and Wuani tests was recorded as follows:
1) hepatocellular jaundice, 0% and 71%, resp.;
2) obstructive jaundice (intrahepatic, cholestasis and posthepatic jaundice), 92% and 25%, resp.;
3) nonjaundiced patients, 8.3% and 13%, resp.;
and 4) healthy subjects, 1.7% and 5.0%, resp.
It is concluded that Jirgl's reaction, with its

high positivity (92%), is useful as an indication of the presence of obstructive jaundice; Wuani's test, although less positive (71%), appears to indicate the presence of hepatic injury (inflammatory or degenerative changes). Intrahepatic cholestasis, in turn, is said to be indicated when both tests are positive; extrahepatic cholestasis, when Jirgl's reaction is positive and Wuani's negative.

8632 NEW METHOD OF PALLIATION OF NEOPLASTIC OBSTRUCTIVE JAUNDICE. (E.) Tulcinsky, B. D. (Tel Aviv U. Med. Sch., Israel). Surgery 61(5):672-673, 1967.

Two cases of transtumor intubation of the common bile duct and 1 case of hepatojejunostomy are described. At surgery, a 62-yr.-old woman with obstructive jaundice was shown to have an infiltrating tumor of the common bile duct, patent only at its upper end. A stiff rubber tube (diameter 0.6 cm) was introduced through a high choledochotomy and advanced through the tumor into the duodenum; the choledochotomy was closed over its upper end in the patent portion. Jaundice regressed rapidly and there was no recurrence until death from cachexia after 8 mo. A 57-yr.-old woman showed a thickened gallbladder, metastases in the liver around the gallbladder area, invasion of the common duct. The gallbladder was removed with a large portion of the liver bearing metastases; a stiff rubber tube was advanced through the patent end of the common duct through the tumor into the duodenum. Jaundice and bile loss ceased within 3 mo. At laparotomy for pyloric obstruction after 9 mo., no metastases were found in the left side of the abdomen; a hard mass, probably neoplastic, on the right side was left untouched; the patient remains in good condition. Three others were similarly treated, with good results in all. In a patient with total occlusion of the extrahepatic ducts with considerable dilatation of the intrahepatic ducts, one end of a polyethylene tube was secured to a 3 mm-wide duct in the left lobe; the other end was inserted into a loop of the small intestine, brought up, and fixed to the liver. Jaundice ceased and the patient lived for 3 mo. Jaundice was relieved in 3 of 4 additional cases treated similarly. The palliative effects of the 2 procedures are stressed.

8633 MALFUNCTION WITHOUT CONSTRICTION OF THE COMMON BILE DUCT. (E.) Wyatt, A. P. (U. California Med. Ctr., San Francisco), F. O. Belzer and J. E. Dunphy. Amer. J. Surg. 113(5):592-598, 1967.

Nine goats survived 2 consecutive operative procedures for the production of traumatic stricture of the common bile duct, and in all cases a satisfactory lumen was restored. In 7, alkaline phosphatase and bilirubin levels were measured, and percutaneous cholangiograms were obtained by needle puncture of the gallbladder. The 7 were sacrificed at varying intervals; the other 2 are alive 6 mo. after operation; 6 of the 7 li for 10 wk. or longer before sacrifice. Alkali phosphatase rose after injury to the duct, fel to within normal limits after repair of the stricture and rose again within a few wk. to a new high. Recurrence of strictures was not ob served; on cholangiographic examination and at autopsy, the diameter of the strictured region of the duct was invariably greater than that f at the repair operation. End-to-end repair of the normal duct and patch grafting of the norm duct after excision of all but a thin posterio strip did not result in malfunction. Circumfe tial scarring, although not narrowing the duct may have interfered with intrinsic function. dogs, 2 silastic catheters were passed into th bile duct, 1 for a short distance upwards, the other downwards toward the sphincter of Oddi. Repeated experiments in which the pressure was raised and lowered in the upper bile duct and gallbladder gave no consistent results with pr sure of 0-30 cm water (or even up to 80 cm). When the fundus of the gallbladder was squeeze by closing the jaws of a hemostat on it, a def increase in flow through the sphincter of Oddi was observed, and the response increased with increasing closeness of the stimulus to the co mon duct. The positive responses obtained we 2- to 4-fold increases in flow, occurring wit 20-30 sec., and often lasting more than 1 min before flow returned to previous rate. Elect stimulation (10 volts at 5 pulses/sec., each 50 msec.) produced a response similar to that seen with the mechanical stimuli. The mechan of this response was nervous since it was abo by infiltration of 2% procaine around the com bile duct.

8634 BILIARY REACTION AND CHOLEDOCHOLITH INDUCED IN THE RAT BY LITHOCHOLIC A (E.) Zaki, F. G. (U. Minnesota Med. Sch., Minneapolis), J. B. Carey, Jr., F. W. Hoffbau and C. Nwokolo. J. Lab. Clin. Med. 69(5):737 748, 1967.

Male Holtzmann rats were divided into 4 group of 36 rats each according to the following di regimen: Group 1, laboratory chow (containin 20% crude protein and 2.5% fat) plus lithocho acid (25, 50 and 75 mg/rat/day) for 15 wk.; Group 2, a low protein diet (containing 6% ca and 6% alpha protein) plus lithocholic acid (75 mg/rat/day) for 15 wk.; Group 3, a low pr diet plus lithocholic acid as in Group 2, the the low protein diet without lithocholic acid for an additional 15 wk.; and Group 4, labora chow plus lithocholic acid (75 mg/rat/day) fo 7-10 wk., then the low protein diet plus lith cholic acid (75 mg/rat/day) for 8-15 wk. Six control animals for each group were fed the c responding diet without lithocholic acid. Se Group 1 animals were subjected to a two-third partial hepatectomy. The addition of lithoch acid to a low protein diet induced hydropic d generation of hepatic cells and an inflammato

on accompanied by ductular cell proliferation
xtended between portal spaces, linking them
er. The common bile duct became greatly
ed and filled with soft concretions which
hardened to form large stones; the mucosa
duct became hyperplastic. The stones were
ed mainly of lithocholic acid and its
lite, $3\alpha,6\beta$-dihydroxy-5β-cholanoic acid;
cter predominated in the stone and also ap-
in high conc. in the serum. All of these
s were reversed when lithocholic acid was
awn from the low protein diet, except for
rge gallstones which remained.

ACALCULOUS CHOLECYSTITIS. (E.)
Munster, A. M. (Peter Bent Brigham
Boston, Mass.) and J. R. Brown. *Amer. J.*
113(6):730-734, 1967.

cases of acalculous cholecystitis were
among 541 cases reviewed in an effort to
pathologic aspects, incidence, prognosis,
sociation with other disease, and to con-
improved management of the condition. The
es (6 men and 6 women), representing a 2.2%
nce, were the only ones to answer the
ia of selection: confirmed absence of
, and absence of biliary tract tumors. Con-
ble clinical and pathologic variation was
although the equal sex distribution followed
eported in the literature. An apparent
ation with other disease, especially pan-
tis, was noted. The 41% incidence of as-
ed disease (noted in liver biopsy) suggests
n acalculous cholecystitis the gallbladder
involved with more widespread disease. No
sion was reached concerning the advisability
oval of the acalculous gallbladder. It
ggested that postoperative morbidity might
roved by searching for hidden associated
ogy by: 1) intraoperative survey; 2) liver
; 3) choledochogram; 4) bacteriologic cul-
f the gallbladder wall; 5) stool cultures
lmonella typhi; 6) postoperative serial
tion of serum amylase, glucose tolerance
and perhaps a lupus erythematosus cell
ation; and 7) close follow-up.

PERSONAL EXPERIENCES WITH 1261 CASES
OF ACUTE AND CHRONIC CHOLECYSTITIS AND
LITHIASIS. (E.) Meyer, K. A. (Northwestern
d. Sch., Chicago, Ill.), N. J. Capos and
Mittelpunkt. *Surgery* 61(5):661-668, 1967.

ubjects were 1261 patients (788 women, av.
yr.; 473 men, av. 50 yr.) who underwent 1274
tions. .The number of patients and deaths
ch age group, resp., were: 10-20 yr. (21,0);
(65,0); 31-40 (116,0); 41-50 (306,0); 51-60
5); 61-70 (202,8); 71-80 (104,7); 81-90
); total 23 deaths (1.8%). The presenting
and symptoms consisted of pain, usually in
ight upper quadrant (72%); belching, food
erance (53%); nausea and vomiting (44%);
ry of jaundice (10%); fever and chills
(6.1%); asymptomatic (6%). In the 76 asymptomatics, gallstones were usually discovered on examination for an associated illness or as an incidental operative finding. Diagnosis was made most frequently by oral cholecystogram: 68% had a nonvisualizing gallbladder, some even after a double dose; stones were observed in 20%; in 12% diagnosis was established without benefit of X-ray. Among the function tests, only serum alkaline phosphatase was useful, being elevated in 74% of those with common duct stones. At operation, 61% claimed this was the first acute attack; 29% claimed a previous attack; 10% claimed 2 or more previous episodes. The av. time that the patients were aware of diseased gallbladder was, for acute cholecystitis, 4.8 yr.; chronic cholecystitis, 5.9; choledocholithiasis, 6.9. The number of patients and percentage mortality and morbidity in the various operative procedures, resp., were: cholecystectomy, acute (198, 3%, 15%), chronic (680, 0.7, 7.0), total (878, 1.2, 9.4); cholecystostomy, acute (18, 11, 22), chronic (38, 2.6, 18), total (56, 5, 19); cholecystectomy and choledochostomy, acute (29, 10, 31), chronic (286, 1.7, 14), total (315, 2.5, 13); choledochostomy, (25, 1.4, 0); total procedures (1274, 1.8, 11). Number of deaths and complications due to cardiovascular-pulmonary causes were 11 and 57, resp.; related to surgery or biliary tract disease, 12 and 86, resp. Final diagnosis with number of patients and percentage mortality, resp., was: acute cholecystitis (227, 3.9%); chronic cholecystitis (878, 0.9); acute cholecystitis with choledocholithiasis (18, 11); chronic cholecystitis with choledocholithiasis (126, 2.3); choledocholithiasis (19, 5); carcinoma of the common duct (2, 0); normal common duct (4, 0); total cases with acute inflammatory disease (245, 4.5); total cases with chronic inflammatory disease (1,029, 1.1). Nonfatal postoperative complications were: atelectasis and pneumonia (27); pulmonary embolus (4); thrombophlebitis (9); cystitis (11); pyelonephritis (3); myocardial infarction (9); cerebrovascular accident (5); gastrointestinal bleeding (2); wound infection (21); bile peritonitis (8); subphrenic or subhepatic abscess (5); pancreatitis (13); cholangitis (4); septicemia (2); ventral hernia (3); intestinal obstruction (3); persistent ileus (6); congestive failure (3); biliary fistula (5); total (143). Because of the progressive nature of cholecystitis, surgery is recommended immediately in those with inflammatory and calculous disease of the biliary tract.

8637 EXPERIMENTAL CHOLELITHIASIS AND LIVER LIPIDS IN RABBITS. INFLUENCE OF ETHANOL. (E.) Borgman, R. F. (Clemson U., S. C.) and F. H. Haselden. *Arch. Path. (Chicago)* 83(5):411-414, 1967.

Groups of New Zealand rabbits consisting of 5 males and 5 females each were formed by dividing litters between groups. Group 1 was fed a commercial rabbit ration (sterol ester fraction of liver ether extracts after 12 wk. on this diet was 80.3% of lipid fraction, triglyceride, 8.2%, free fatty acid, 3.8% and phospholipid fraction, 5.1%);

Group 2 received a purified ration containing 15% olive oil as the total fat source (sterol ester fraction of liver ether extracts after 12 wk. on this diet was 79.7% of lipid fraction, triglyceride, 12.7%, free fatty acid, 2.5% and phospholipid, 5.3%); and Group 3 received the same purified ration (sterol ester fraction of liver ether extracts after 12 wk. on this diet, 74.5%, triglyceride, 12.4%, free fatty acid, 5.3% and phospholipid, 5.5%) plus 15% ethanol in the drinking water. Animals received these rations for a 12-wk. trial period. Animals of Group 1 had normal livers, while those of Groups 2 and 3 had fatty degeneration, although those of Group 3 had less degeneration than those in Group 2. Liver lipid fractions were only modestly influenced by the treatments. The triglyceride percentages of the purified ration groups were greater than that of the commercial ration group, i.e., 12.4-12.7 compared with 8.2%. In Group 3, the sterol ester fraction was slightly less and the free sterol fraction greater than in the other groups. The fatty acid percentages of the liver lipid fraction varied both by fraction and by diet, as indicated earlier in brackets, but ethanol had only a minor effect. Rabbits in Groups 2 and 3 developed gallstones of the cholesterol type, but the ethanol had no definite influence on their formation. Rabbits fed a gallstone-producing diet (Groups 2 and 3) had lower 18:2 percentages in the liver sterol ester fraction than rabbits fed a commercial ration.

8638 SURGICAL MANAGEMENT OF SOLITARY ADENOMYOMA OF THE GALLBLADDER. (E.) Tompkins, R. K. (Ohio State U. Sch. Med., Columbus). Amer. Surg. 33(5):415-418, 1967.

Of 7 cases of adenomyoma of the gallbladder diagnosed over 18 yr., 5 were treated surgically; 3 of these were correctly diagnosed preoperatively; 3 had symptoms referable to the biliary system. Two who refused surgery have been followed for 6 and 13 yr. resp., and continue to have epigastric distress. In the patient followed longer, repeated cholecystograms failed to show a change in the gallbladder lesion. Opinion is divided in the literature as to whether cholecystectomy should be performed for asymptomatic adenomyomata. Decision to delay cholecystectomy should be based upon certainty of diagnosis by X-ray and absence of symptoms. It is considered that filling defects of the wall of the gallbladder should be treated by cholecystectomy if only to establish the diagnosis and to prevent possible future symptoms. The rate of malignant degeneration in an adenomyoma does not appear to be higher than that seen in normal gallbladder mucosa.

8675 USE OF BIOLOGY IN HEPATOBILIARY DISEASE. (Fr.)(Rev.) Albot, G. (Med. Coll., Paris) and J. Lunel. Rev. Prat. (Paris) 17(15):2199-2244, 1967.

8676 BENIGN TUMORS OF THE BILIARY TRACT. 5 PERSONAL OBSERVATIONS. (It.) Infranzi, A. (U. Naples, Italy), R. Pusateri, M. Abbate and D. Mori. Gazz. Int. Med. Chir. 72(11):893-935, 1967.

8677 CURRENT STATISTICS, CARCINOMA OF THE GALLBLADDER. AN ELEVEN-YEAR-REVIEW OF CASES FROM THE HARRISBURG POLYCLINIC HOSPITAL. (E.) Classen, D. J. (Harrisburg Polyclin. Hosp., Pa.). Pp. 37-41 in Polyclin. J. (Harrisburg), Summer, 1967.

8678 PANCREATODUODENECTOMY FOR PERIAMPULLARY CANCER. (E.) Warren, K. W., M. C. Veidenheimer and H. S. Pratt. Surg. Clin. N. Amer. 47(3):639-645, 1967.

8679 MALIGNANT NEOPLASMS OF THE BILE DUCTS. (E.) Braasch, J. W., K. W. Warren and G. A. Kune. Surg. Clin. N. Amer. 47(3):627-638, 1967.

8680 TEN YEARS EXPERIENCE WITH GALLBLADDER CARCINOMA. (Hun.) Dohanics, S. and R. Exterde. Magy. Sebesz. 20(30):167-171, 1967.

8681 SPONTANEOUS BILIO-BILIARY FISTULA. (It.) Gullino, D. (U. Turin, Italy) and G. Trotti-Maina. Minerva Chir. 22(9):543-
1967.

8682 BILIARY-DIGESTIVE TRACT FISTULAS. 3
CASES. (Fr.) Adloff, M. (Surg. Cli
B, Strasbourg, France), M. Gillet and A. G. We
Ann. Chir. 21(9-10):497-507, 1967.

8683 ANOMALIES OF THE BILE PASSAGES COMBI
WITH ACUTE GALLBLADDER PERFORATION.
(E.) Zwaveling, A. (Univ. Hosp., Leiden,
Netherlands), A. S. J. Botenga and E. M. Vroom
Brit. J. Radiol. 40(475):528-532, 1967.

8684 SO-CALLED "GALLBLADDER REGENERATION"
AND ITS ORIGIN. (Ger.) Kainberger,
(Barmherzigen Bruder Hosp., Salzburg, Austria)
Radiol. Austria. 17(1):5-12, 1967.

8685 VALUE OF THE JIRGL TEST IN THE DIAGN
OF JAUNDICE. (Fr.) Tête, M. R.,
M. Danjoux, J. Evreux, B. Savoye, A. Vachon an
M. Angelvy. Rev. Lyon Med. 16(8):341-351, 196

8686 ARTERIAL INTERRUPTIONS OF THE TRUNK
BRANCHES OF THE HEPATIC ARTERY ASSOC
WITH POSTOPERATIVE STENOSIS OF THE MAIN BILE D
(Fr.) Hepp, J., H. Bismuth and C. Hernandez.
Lyon Chir. 63(3):449-452, 1967.

8687 DISAPPEARING GALL-STONES. (E.)
Margulies, S. I. (Johns Hopkins U.,
Baltimore, Md.), B. G. Brogdon, R. A. Sindler
F. R. Perilla. Brit. J. Radiol. 40(475):546-548, 1967.

8688 CHOLESTEROL-SOLUBILIZING AGENTS RELA
TO THE GALLSTONE PROBLEM. (E.) Ainsworth, C. (Lilly Res. Lab., Indianapolis, Indiana), D. N. Benslay, J. Davenport, J. L. Hudson, D. Kau, T. M. Lin and R. R. Pfeiffer. J. Med. Chem. 10(2):158-161, 1967.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis and Metabolic Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication of GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available, free to qualified interested investigators and practitioners, citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology had accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis and Metabolic Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published. Requests from qualified individuals to receive free copies of this publication, and address changes and other communications from these individuals should be addressed to:

GENERAL

9 STUDIES ON KALIKREINS. I. THE EFFECTS
OF GASTROINTESTINAL SYSTEM AND THE
ER ON PANCREATIC KALLIKREIN. (E.) Moriya, H.
. U. Tokyo), C. Moriwaki, S. Akimoto and
Yamazaki. Chem. Pharm. Bull. (Tokyo) 15(4):
-402, 1967.

likrein, extracted from the hog pancreas
-80 Frey U/mg) was examined for esterase and
omotor activities. It was tested in pooled
an gastric juice, in pooled human intestinal
ce, with rat liver slices, and was properly
fered at 37 ℃ for esterase activity. The
erase activity normally present in human
estinal juice was measured without the
ition of kallikrein as a proper control. For
n test, hog pancreatic extract from 0.5-1.5
was used. The vasomotor activity was measured
dog assay of the hog pancreatic extract
ectly, of the extract incubated with human
tric juice and human intestinal juice. The
odilator action of kallikrein was measured in
incubated liver slice medium. As the
erase activity of kallikrein extract decreased
the presence of various conc. of gastric juice
ing a 120-min. period, the vasodilator
ivity of the preparation also decreased.
re kallikrein was present in intestinal juice,
esterase activity of the kallikrein prepara-
n remained almost constant, as did the
odilator activity. No change occurred in
her property of the extract when incubated
h liver slices. The 2 properties, those of
esterase and a vasodilator, seemed to vary in
ctly the same degree and same direction in
se preparations and were of parallel strength
different extracts; thus these properties
ht be common to the same molecule. However,
re might be adsorption of one substance upon
ther, each having a different property. Two
ferent molecules might also be involved, each
h a different activity but with similar
sical characteristics and thus being extracted
ether.

0 PROPERTIES OF A NEW SYSTEM OF AMINE-
STORING CELLS IN THE GASTRIC MUCOSA OF
RAT. (E.) Håkanson, R. (U. Lund, Sweden),
Lilja and C. Owman. Europ. J. Pharmacol.
):188-199, 1967.

arge system of cells, structurally similar to
enterochromaffin cells of the stomach wall,
detected in the epithelium of the entire
ndular portion of the rat stomach after i.p.
in. of the amino acid precursor, L-3,4-di-
lroxyphenylalanine (L-DOPA, 100 mg/kg). This
tem of enterochromaffin-like cells normally
ores neither catecholamines nor serotonin but
take up L-DOPA by an active mechanism which
blocked by pretreatment with i.p. admin. of
mg/kg of cocaine. Previous inhibition of the
carboxylating enzyme with either 200 mg/kg of
(DL-seryl)-N-2,3,4-trihydroxybenzyl-hydrazine,
200 mg/kg of 4-bromo-3-hydroxybenzyloxyamine or 100 mg/kg of *m*-hydroxybenzylhydrazine diminished the fluorescence, indicating that L-DOPA is not retained in the cytoplasm unless it has been decarboxylated to dopamine. The intensity was increased after pretreatment with either 200 mg/kg of Pargyline (N-methyl-N-(2-propynyl) benzylamine) or 100 mg/kg of nialamide. In addition, these reserpine-resistant cells were triangular or flask-shaped, and were located between the columnar epithelial cells with their necks projecting towards the lumina of the gastric glands. The green fluorescence was diffusely distributed in the cytoplasm and conc. in the basal part of the gland.

8691 THE EFFECT OF HYPOPHYSECTOMY IN THE WEANLING RAT ON SIZE OF THE SUBMANDIBULAR GLAND AND ON SALIVARY PROTEINS. (E.) Carbone, D. F. (Harvard Sch. Dent. Med., Boston, Mass.), E. A. Sweeney and J. H. Shaw. Arch. Oral Biol. 12(6):721-731, 1967.

White rats (21 days old) were divided into 22 control and 28 experimental animals. The experimental rats were hypophysectomized by the parapharyngeal approach, weighed 3 times/wk. and their food consumption measured daily. At 80 days of age saliva was collected by a standard procedure after s.c. inj. of pilocarpine HCl (7.5 mg/kg) and total salivary protein conc. was determined for all animals. Serum was also obtained from each rat. Salivary and serum proteins were separated by paper electrophoresis. The animals were killed; the submaxillary and sublingual glands, thyroid, adrenal gland, testes and ovaries were excised and weighed. Hypophysectomy in the weanling rat resulted in major reductions in the growth rate, food consumption and relative wt. of endocrine target organs as compared to intact rats. The ratios of the wt. of the submandibular gland complex to body wt. were similar for hypophysectomized and normal rats; the size of the submandibular and sublingual glands was not uniquely dependent upon the pituitary gland hormones. Pilocarpine-stimulated salivary secretion and the total salivary protein were closely related to body wt. and to submandibular gland wt. in normal and hypophysectomized rats. Salivary protein conc. tended to be elevated in hypophysectomized rats. Altered conc. of protein components of saliva were noted in the experimental animals with marked increases of the anodal migrators.

8692 INFERIOR VENA CAVAL OBSTRUCTION FROM INCREASED INTRA-ABDOMINAL PRESSURE. EXPERIMENTAL HEMODYNAMIC AND ANGIOGRAPHIC OBSERVATIONS. (E.) Rubinson, R. M. (Nat. Heart Inst., NIH, Bethesda, Md.), J. S. Vasko, J. L. Doppman and A. G. Morrow. Arch. Surg. (Chicago) 94(6):766-770, 1967.

In 12 anesthetized normal dogs, pressures were recorded from catheters placed in the inferior vena cava immediately above and below the diaphragm and in the peritoneal cavity; intra-abdominal vol. was then acutely increased by serial inj. of glycerine-saline or air into the peritoneal cavity. After inj. of 100-150 ml/kg of fluid or air, there was a pressure gradient of 2-5 mm Hg between the 2 segments of the inferior vena cava; after the intra-abdominal vol. had been increased to 200-220 ml/kg, the av. pressure gradient was 28 mm Hg. Contrast radiographs showed progressive narrowing and angulation of the inferior vena cava at the diaphragm. In 3 dogs thoracic inferior vena caval flow was also measured, and varied inversely with the magnitude of the pressure gradient. Pressure and flow rapidly returned to control levels when the i.p. fluid was removed; intra-abdominal pressure fell. Acute abdominal distention of sufficient severity to elevate the intra-abdominal pressure, seems to result in obstruction of the inferior vena cava at the diaphragm. This functional and reversible form of inferior vena caval obstruction has occurred in patients, and its possible clinical importance is discussed.

8693 ACTION OF CARBAMYLCHOLINE ON THE STRIATED DUCTS GLYCOGEN IN MAMMALIAN SALIVARY GLANDS. (E.) Fava-De-Moraes, F. (U. Sao Paulo, Brazil), R. Giuffrida and L. C. U. Junqueira. Acta Histochem. (Jena) 27(1):1-8, 1967.

8694 TESTOSTERONE INDUCTION OF ESTEROPROTEOLYTIC ACTIVITY IN THE MOUSE SUBMAXILLARY GLAND. (E.) Angeletti, R. A. (Washington U., St. Louis, Mo.), P. U. Angeletti and P. Calissano. Biochim. Biophys. Acta 139(2): 372-381, 1967.

8695 FRACTIONATING OF SALIVARY GLYCOPROTEINS. (Fr.) Havez, R. (Fac. Med., Lille, France), A. Carlier-Vanneuville, C. Carlier and Y. Moschetto. C. R. Soc. Biol. (Paris) 161(2): 325-330, 1967.

8696 THE EFFECT OF AGING ON THE HISTOCHEMISTRY OF THE RAT SUBMANDIBULAR GLAND. (E.) Bogart, B. I. (New York U., N. Y.). J. Geront. 22(3):372-375, 1967.

8697 SALIVARY GLAND ENLARGEMENT IN RATS AFTER ADMINISTRATION OF THEOPHYLLINE. (E.) Wells, H. (Harvard Sch. Dent. Med., Boston, Mass.). Amer. J. Physiol. 212(6):1293-1296, 1967.

8698 VASOACTIVE SUBSTANCES AND THE GASTROINTESTINAL TRACT. (E.)(Rev.) Haverback, B. J. (U. Southern California Sch. Med., Los Angeles) and B. J. Dyce. Gastroenterology 53(2):326-331, 1967.

8699 EFFECT OF X-RAY IRRADIATION ON THE INTENSITY OF RADIOACTIVE METHIONINE INCORPORATION IN GASTRIC MUCOSA PROTEINS. (Uk. Sukhomlinov, B. F. (Lenin State U., Lvov, USSR) and Ia. P. Chaika. Ukr. Biochim. Zh. 38(5): 532-538, 1966.

VASCULARIZATION OF THE HEPATIC AND
COMMON BILE DUCT. (ANATOMIC AND
AL PROBLEMS OF COMMON BILE DUCT PATHOLOGY).
D'Addato, M. (U. Bologna, Italy), E.
ili and L. Baldelli. Riv. Gastroent.
185-200, 1966.

ood supply of the common bile duct was
d by an angioplastic technic using plastic
in 15 anatomical specimens obtained at
y. Frequent controls were undertaken to
that no macroscopic evidence of biliary
or hepatic artery pathology was present.
as taken that the peri-biliary area re-
intact and that its normal connections
he liver, stomach, duodenum, hepatic
(origin), and hepatoduodenal ligament
reserved. Findings were not always con-
t in all specimens. The supra-duodenal
n of the common bile duct received its
supply from the supraduodenal artery,
frequently arose from the retroduodenal
. The supraduodenal artery gave off an
ing branch (Wilkie's artery) which in turn
few slender branches to the anterior sur-
f the cystic and common bile ducts. In
ases, the posterior surface of the common
uct received 2 ascending branches, 1 from
praduodenal and 1 from the gastroduodenal
. On the other hand, great consistency
ted in the blood supply of the intra-
atic portion of the common bile duct by
of the retroduodenal artery, which also
ranches to part of the supraduodenal por-
The retroduodenal artery consisted of an
nt vascular network and was much larger
he supraduodenal artery. A much more
us blood supply was observed in the intra-
atic portion than in the supraduodenal por-
f the common bile duct. The most highly
arized surfaces were the right lateral and
ior. The supraduodenal portion of the
bile duct is probably most suitable for
ochotomy, especially the anterior surface
the point of entry of the cystic duct.

INTRAORGAN INNERVATION OF THE LIVER.
(Rus.) Azarova, A. M. (Kharkov Med.
USSR). Arkh. Anat. 52(2):72-77, 1967.

rgan liver nerves were studied by the
microscopic method of V. P. Borob'ev in 6
preparations obtained from subjects who
ed from various diseases. Intraorgan
c innervation was accomplished by way of
ior and posterior hepatic plexuses, branches
e vagus nerve from the gastric plexus and
branches which accompany the inferior
cava. The distribution of nerves which
pany the hepatic artery and the vena porta
the liver follows the segmental distribution
ese vascular tributaries. The vascular-
l nodules of the portal tract cross at
angles with the branches of the hepatic
veins; in the region of such crossings, a close contact occurred between the vascular-neural nodules of both the portal tract and the hepatic veins. Both venous systems repeatedly crossed each other in the depth of the liver. With these venous systems there were large accumulations of connective tissue; the larger portion belonging to the portal tract nodule, and the smaller portion to the hepatic vein. Such crossings of branches of the 2 venous systems in the left hepatic lobe were found constantly and almost regularly in one and the same parts. In the right lobe, the crossings were noted only in the peripheral portions of the liver. No combination of the nerves of the portal tract nodules and nerves in the wall of the hepatic veins was observed.

8710 ENDOPLASMIC RETICULUM AND THE ORIGIN OF MICROBODIES IN FETAL MOUSE LIVER. (E.) Essner, E. (Sloan-Kettering Inst. Cancer Res., New York, N. Y.). Lab. Invest. 17(1):71-87, 1967.

The form and distribution of bile canaliculi, Golgi apparatus and lysosomes in 18-day fetal mouse (C3H/MIL; C3H/An inbred strains) liver were studied in frozen sections intubated for phosphatase activities that delineate these organelles. Two interrelated changes in fine structure of the parenchymatous cells were described; 1) extensive dilatation of terminal regions of the rough endoplasmic reticulum and accumulation of amorphous material, presumably secretory, within them; and 2) increase in the number of microbodies occurring in close association with the dilatations of reticulum. Orientation of the endoplasmic reticulum toward the Golgi apparatus suggested the possibility of movement of secretory material from the dilatations of endoplasmic reticulum to the Golgi apparatus. Spatial association, structural similarities and direct continuities between microbody membrane and endoplasmic reticulum suggested that the microbodies arose from dilatations of the reticulum. On the basis of these findings a sequence is proposed for the formation of microbodies from dilations of the endoplasmic reticulum in the parenchymatous cells of the fetal liver.

8711 STRUCTURE AND SIZE OF CANINE COMMON BILE DUCT. (E.) Mahour, G. H. (Mayo Clin., Rochester, Minn.), K. G. Wakim, E. H. Soule and D. O. Ferris. Arch. Surg. (Chicago) 95(2): 241-244, 1967.

8712 INTRAORGAN LYMPHATIC SYSTEM OF STOMACH IN SOME SPECIES OF AMPHIBIA AND REPTILES. (Rus.) Balashev, V. N. (Leningrad Med. Inst., Sanit.-Hygiene, USSR). Arkh. Anat. 52(6): 57-64, 1967.

8713 ETIOLOGY OF ANEMIA IN THE JAPANESE. II. INFLUENCES OF DIETARY PROTEIN ON IRON ABSORPTION. (Jap.) Miyata, S. (Toho U., Tokyo). Nippon Ketsueki Gakkai Zasshi (Acta Haemat. Jap.) 29(6):845-849, 1966.

Rats were divided into 2 groups: Group 1 received ordinary solid food containing animal protein; Group 2 received a special diet containing defatted soy bean protein instead of animal protein. The protein content of both foodstuffs was equivalent. The rat small intestine was ligated by the Laszt method, and a vol. (amount unspecified) of $FeCl_3$ mixed with $^{59}FeCl_3$ as a tracer was infused into the ligated intestine; 90 min. later, Fe absorption was studied by measuring the Fe content of intestinal contents and of the intestinal wall. No difference in Fe absorption was found between the 2 groups when animals were fed for only 1 or 2 days; however, after 7, 14 and 21 days, there was a marked decrease in Fe absorption in animals which received no animal protein. It is concluded that the quality of protein in the daily diet influences the absorption of Fe.

8714 STUDIES ON INTESTINAL ABSORPTION OF HYDROXYCOBALAMINE II. BIOLOGICAL HALF LIFE OF HYDROXYCOBALAMINE IN SMALL INTESTINAL WALL. (Jap.) Abe, T. (Tokyo Med. Dent. U.), T. Nakajima and H. Okamura. Nippon Ketsueki Gakkai Zasshi (Acta Haemat. Jap.) 29(6):874-878, 1966.

Hydroxycobalamine, admin. i.m., is absorbed slowly from the site of inj. compared with cyanocobalamine. The biological half-life of these substances was studied in the small intestine of rabbits. They received 0.1 μg/kg p.o. of either ^{57}Co-hydroxycobalamine or ^{57}Co-cyanocobalamine, and were sacrificed at 1, 6, 12, 18 and 24 hr. after admin. in order to estimate the uptake of ^{57}Co in the proximal, middle and distal portions of the small intestinal wall. The distal third of the small intestine had the highest activity at each time interval after admin. of either agent. The biological half-lives of hydroxycobalamine and cyanocobalamine in the whole small intestinal wall were 50 and 9 hr., resp., while those of the distal third of the wall were 11 and 6 hr., resp. It is concluded that hydroxycobalamine has a longer biological half-life in the small intestinal wall than cyanocobalamine.

8715 CLINICAL STUDIES ON IRON ABSORPTION. REPORT I. FERROUS SULFATE ABSORPTION TEST. (Jap.) Yamaba, M. (Kyoto U., Japan). Naika Hokan (Jap. Arch. Intern. Med.) 13(11): 495-505, 1966.

An aqueous soln. of 5 mg ferrous sulfate (1 mg as Fe) combined with 5-10 μc of $^{59}FeCl_3$ and 100 mg of ascorbic acid was admin. p.o. to fasting subjects early in the morning, and the Fe absorption rate was determined in feces and RBC. With regard to measurement, the amount of ^{59}Fe excretion in feces was determined within a range of error of approx. 3% by repeated measurement on an accurately weighed, thoroughly mixed sample of feces; the amount of ^{59}Fe uptake by RBC could similarly be determined within a range of error of approx.
by repeated measurement on a 2-ml blood sampl
The daily activity of ^{59}Fe excreted in feces
p.o. admin. was less than 1% of the admin. am
within 10 days; thus it is considered adequat
collect fecal specimens 10 days after p.o. ad
In 8 normal subjects, the av. rate of Fe abso
tion, calculated by the feces method, was
30.8 ± 3.0%, and by the RBC method, 17.5 ± 6.
In order to study the difference between the
absorption rate obtained by the feces method
that obtained by the RBC method, the distribu
of ^{59}Fe in the body was studied in normal rat
after admin. of radioactive ferrous sulfate l
with ^{59}Fe. Approx. 10% of the ^{59}Fe taken up
the RBC was distributed in the liver, small i
testines, etc. A significant correlation was
between Fe absorption rates obtained by the f
method and by the RBC method. Compared with
subjects, 10 cases of Fe deficiency anemia ha
greater Fe absorption rates, i.e., 53.1 ± 22.
by the feces method and 45.5 ± 20.1% by the F
method. The rate of Fe absorption significar
correlated with the serum Fe conc. and with t
hemoglobin value, but not with the degree of
acidity in the gastric juice. The Fe absorpt
rate was almost normal in patients with post-
gastrectomy anemia and with Banti's syndrome,
and was slightly low in patients with chronic
hepatitis. The Fe absorption rate of patient
with asplastic anemia was nearly normal by th
feces method.

8716 CLINICAL STUDIES ON IRON ABSORPTIOI
REPORT II. EGG IRON ABSORPTION TES
(Jap.) Yamaba, M. (Kyoto U., Japan). Naika
Hokan (Jap. Arch. Intern. Med.) 13(12):519-5
1966.

The rate of Fe absorption was determined by
both the feces and RBC methods after p.o. adm
of 55 g of egg (used as a model food) labelec
with ^{59}Fe (1.27 mg as Fe) in fasting subjects
and the findings were compared with values pr
viously obtained of the rate of ferrous sulfa
absorption. As determined in 9 normal subjec
the rate of Fe absorption was 16.1 ± 5.66% by
the feces method and 4.9 ± 1.4% by the RBC me
The rate of Fe absorption in 15 patients with
Fe-deficiency anemia was 20.6 ± 10.3% by the
feces method and 12.8 ± 10.5% by the RBC meth
These rates of egg Fe absorption had a signif
correlation with the degree of acidity of gas
juice, but not with the hemoglobin value or t
amount of Fe in the serum. When patients wer
subdivided according to the degree of acidity
of the gastric juice (anacidity-hypoacidity,
normoacidity-hyperacidity), the rate of Fe ab
sorption was almost normal in the first group
and was high, with a statistically significar
difference from normal values, in the second
group. The Fe absorption rate in patients wi
postgastrectomy anemia was low, with a statis
ally significant difference from normal value
and the Fe absorption rate of patients with B
syndrome, chronic hepatitis and aplastic anem
was almost the same as normal values. The fe

ate absorption test and the egg Fe absorption were performed in the same patients in order otain a comparative study of both Fe absorp- rates. In normal subjects, the absorption of egg Fe (RBC) was less than half that of ous sulfate absorption. In patients with eficiency anemia, absorption of egg Fe was , almost to the same degree as in normal ects. Those patients with hypo- or anacidity cially had markedly low values in the rate of Fe absorption. In patients with postgastrectomy ia, absorption of egg Fe was extremely poor pite of good absorption of the Fe salt. In ents with Banti's syndrome, chronic hepatitis aplastic anemia, absorption of egg Fe was , almost to the same degree as in normal ects.

CLINICAL STUDIES ON IRON ABSORPTION.
REPORT III. INVESTIGATION ON VARIOUS
ORS INFLUENCING IRON ABSORPTION. (Jap.)
oa, M. (Kyoto U., Japan). Naika Hokan
. Arch. Intern. Med.) 13(12):529-538, 1966.

absorption tests using ferrous orotate (1 mg e) and ferrous fumarate (1 mg as Fe), both led with radioactive ^{59}Fe, were both performed atients and normal subjects in order to com- the rate of absorption of these organic Fe lexes with that of ferrous sulfate. Another on for these comparisons was that changes in osorption were observed with the addition of rbic acid, with admin. of ferrous fumarate, with reduced glutathione. The state of dis- tion of ferrous orotate and of ferrous rate in gastric juice was studied, indicating the degree of acidity of the gastric juice an important role in isolation of Fe from e compounds. In normal subjects, the rate osorption of these organic Fe complexes was st the same as that of ferrous sulfate. Pa- ts with Fe-deficiency anemia had good ab- tion rates of both of the organic Fe com- es, comparable to rates in normal subjects, showed almost the same values as with ferrous ate. The rates of Fe absorption thus obtained significantly correlated with the degree of ity of the gastric juice. In 2 patients with gastrectomy anemia, these Fe-absorption rates slightly less compared to the rate of ferrous ate absorption. The absorption rates of Fe and without addition of ascorbic acid were ared using ferrous fumarate labeled with ^{55}Fe ^{59}Fe (a daily dose of 150 mg as Fe); the ad- on of ascorbic acid promoted the absorption e. The rate of Fe absorption increased arly as the daily dose of ascorbic acid was eased to 600 mg, 1200 mg and 1800 mg. When ous sulfate was admin., with or without 100 mg lutathione (reduced), the rate of Fe absorp- was increased in the combination which ained glutathione.

STUDIES ON KALLIKREINS. II. PASSAGE
OF ^{131}I-LABELLED HOG PANCREATIC
KALLIKREIN ACROSS THE RAT INTESTINE. (E.)
Moriya, H. (Sci. U. Tokyo), C. Moriwaki and
S. Akimoto. Chem. Pharm. Bull. (Tokyo) 15(4):
403-410, 1967.

Hog pancreatic kallikrein (molecular wt. approx. 33,000) labeled with ^{131}I (66.7 Frey U/mg) was used. A 10-cm jejunal loop was tied off in fasting rats (120 g); 0.2 ml of saline containing 3 mg of ^{131}I-labeled kallikrein (9.6 x 10^6 cpm) was inj. into the loop; 2-3 hr. later the animals were killed by bleeding and the liver, kidney, spleen, thyroid, small intestine and serum were tested for radioactivity in a well-type scintillation counter. Some serum was dialyzed to ascertain if the radioactivity was dialyzable; serum protein was precipitated, the precipitate washed, and its radioactivity measured. Radiopaper chromatographic analysis was also performed to determine purity of the ^{131}I-kallikrein. In vitro experiments on intestinal transfer of ^{131}I-kallikrein were done on everted 10-cm segments of jejunum tied off at the ends, containing 1 ml of Krebs-Ringer soln., placed in 30 ml of the same soln. containing ^{131}I-kallikrein, oxygenated, and maintained at 37°C. After 1 hr. the serosal fluid was removed and radioassayed. Dialysis against water, and radiopaper chromatography were done and the vasodilator activity was determined in the dog. Controls were maintained using KI-K^{131}I. About 54% of the radioactivity remained in the intestinal loops inj. with ^{131}I-kallikrein in vitro whereas those inj. with KI-K^{131}I had little radioactivity remaining in the loop. Of the absorbed radioactivity, most was in the serum after 2 hr. Of the organs, the liver had most, the kidney about half that of the liver, the spleen and thyroid about one-fifteenth that of the liver. About 1.7% of the original radioactivity was in the liver. When ^{131}I-kallikrein was inj. i.v. the liver also had the greatest uptake among the organs examined. In vitro, about 40% of the radioactivity was transferred to the serosal side in 1 hr. No difference in the vasodilator activity of the ^{131}I-kallikrein occurred before or after passage through the intestinal wall, and no difference occurred before and after dialysis of these fractions.

8719 EXPERIMENTAL STUDIES ON ABSORPTION
MECHANISM OF BILE ACIDS THROUGH DOG
GALLBLADDER WALL. (Jap.) Yoshimura, N. (Kyushu
U., Fukuoka, Japan). Igaku Kenkyu (Acta Med.
[Fukuoka]) 36(2):156-171, 1966.

In vitro studies were done in a diffusion apparatus consisting of 2 cylindrical, ported, glass chambers 10 mm in inside diameter and 50 mm long, closed at one end and flanged at the other so that the dog gallbladder mucosa could be clamped between the flanged ends, allowing diffusion through the mucosa from one chamber to the other. In vivo studies were done by perfusing the gallbladder through a specially constructed 2-lumen cannula permitting even perfusion with constant recirculation of the perfusate by a pump. A sampling valve was provided for removal of fluid for analysis. Analysis of bile acids was made by photometry and thin-layer chromatography. Chromatography was also used for determination of other constituents in bile. The soln. pH was constantly checked by potentiometer and the following measurements made: Apparent partition coefficients of bile acids to isoamyl acetate by the equilibrium method, and binding ratios of cholic acid to lecithin and polyoxyethylene sorbitan monooleate were obtained by sack dialysis at several different pH values; The amounts of cholic acid transported through stripped canine gallbladder mucosa were determined in vitro using the diffusion apparatus. The dog gallbladders were perfused in vivo with the bile acid soln. and the absorption rates of the bile acids through the gallbladder mucosa were determined at different pH values. This was done in 51 dogs. Cholic and taurocholic acids were absorbed at rapid rates at pH values lower than the pKa of the bile acids; (pKa was obtained from the Henderson-Hasselbach formula). At pH values higher than pKa, bile acids were poorly absorbed. These results indicate that the passage of bile acids through the gallbladder mucosa occurs as the non-ionized form passing through a lipid barrier. Transport of unconjugated cholic acid was passive; the conjugated bile acid, taurocholic acid was not always passively transported. Cholic and taurocholic acid mixed with surface-active substances such as lecithin and polysorbate-80 were not absorbed through the gallbladder wall even in acidic soln. Apparently large, impermeable micellar complexes are formed. These studies were statistically significant.

8720 ABSORPTION OF GLUCOSE FROM THE COLON AND RECTUM. (E.) Long, C. L. (Columbia U., New York City), J. W. Geiger and J. M. Kinney. Metabolism 16(5):413-418, 1967.

Experiments on colonic and rectal absorption of glucose were carried out in 4 female and 2 male subjects. All the females had colostomies, 3 in the transverse colon and one in the right colon; 1 male had colostomy of the transverse colon, the other male had undergone an operation for hernia and was the subject for the rectal absorption study. ^{14}C-Glucose, uniformly labeled (specific activity 48.65 µc/mM) was dissolved in saline, 20 µc/3.5 ml; and the activity determined in a liquid scintillation counter. The ^{14}C-glucose was admin. by colostomy or rectal tube and was followed by 10-20 ml saline soln. to wash all radioactivity from the tube into the bowel. Single ^{14}C-glucose inj. were made the day after the colonic or rectal absorption study. Neomycin was used to sterilize the gastrointestinal tract of 1 subject; total dosage was 4 g over 48 hr. prior to 1 phase of the absorption study. Expired CO^2_2, O_2 and $^{14}CO_2$ were continuously measured for 3 hr. after a 30-min. base period of measurement of CO_2 prior to ^{14}C-glucose admin. Gas analyses were also made at 3 and 7 hr. after admin. of radioactive glucose. Blood samples were taken each hr. for 5 hr. after isotope admin., and specific activity of glucose was determined in these samples. The percentage of the dose expi as $^{14}CO_2$ was between 14 and 25 in 3 hr. whether ^{14}C-glucose was given by colostomy or rectal tube. ^{14}C-Glucose inj. i.v. produced 17-25% $^{14}CO_2$ in 3 hr. One patient in addition was gi ^{14}C-glucose by nasogastric tube and the amount radioactive CO_2 expired was the same. Very lo blood glucose specific activities were found i all patients when ^{14}C-glucose was given by colo tomy or rectal tube at any time during the stu (less than 0.01 µ/mM glucose). When ^{14}C-gluco was inj. i.v. the specific activity was as hig as 150 times this value in 30 min. and 15 time as high at the end of 3 hr. The rate of entry ^{14}C into the bloodstream from the colon or rec was too low to account for the $^{14}CO_2$ expired i 3 hr. After neomycin therapy the $^{14}CO_2$ was completely eliminated from the breath after ad of ^{14}C-glucose. Glucose is not absorbed as su across the colonic or rectal mucosa, but undergoes bacterial degradation before absorption.

8721 ENZYMIC HYDROLYSIS OF THE CARBON-FLUORINE BOND OF α-D- GLUCOSYL FLUOR BY RAT INTESTINAL MUCOSA. LOCALIZATION OF INTESTINAL MALTASE. (E.) Barnett, J. E. G. (U. Southampton, England), W. T. S. Jarvis and K. A. Munday. Biochem. J. 103(3):699-704, 196

Rat small intestine mucosa was extracted by homogenizing and centrifuging at 26,000 g unti the supernatant was clear. The supernatant wa the extract used in the tests of the enzymic hydrolysis of the carbon-fluorine bond. Many different technics were used: the glucose-oxi methods A and B, glucosyl fluoride hydrolase b release of F⁻, assay of α-D-glucosidase with o-nitrophenyl α-D-glucoside, the mutarotase test, and chromatography. The tissue accumula experiment with the measurement of reducing su and fluorine determination by the microdiffusi method were also used. Alpha-D-Glucosyl fluor was hydrolyzed by the rat intestinal mucosa ex tract. Optimum pH was 6.6 and Km was 0.4 mM a 20°; this hydrolase activity was associated wi both mutarotase and α-D-glucosidase activities Tris (5 mM) inhibited both α-D-glucosidase and α-D-glucosyl-fluoride-hydrolase activities by 55% but did not inhibit mutarotase. K_i of Tri for both enzyme activities was 2 mM. The extr did not hydrolyze melibiose and lactose. The thermal stability of α-D-glucosidase and the α-D-glucosyl fluoride hydrolase was identical while mutarotase was more thermolabile. A preparation of the brush border of intestinal epithelial cells contained both α-D-glucosyl-fluoride-hydrolase and α-D-glucosidase activit In each precipitate and washing the ratio of t 2 activities was the same; all the mutarotase activity was in the 1st supernatant. Agidex, fungal amylglucosidase, cleaved glucosyl fluor in addition to maltose. Tris inhibited both activities and in each case K_i was 3 m N. The probability of identity of α-D-glucosyl fluori

ase and α-D-glucosidase is very high. In-
on of intestinal slices with 1 mM α-D-gluco-
uoride led to complete hydrolysis in 30 min.
ucose rapidly entered the cell and was
lized, leaving the fluorine in the medium.
onstitutes a further proof that intestinal
ucosidase, although located on the brush
, is located outside the site of sugar
transport.

ACTIVE TRANSPORT OF L-SELENOMETHIONINE
IN THE INTESTINE. (E.) McConnell, K. P.
sp., Louisville, Ky.) and G. J. Cho. Amer.
siol. 213(1):150-156, 1967.

ive transport of L-^{75}Se-methionine across
testine of the hamster was found; the
ort rate varied from segment to segment.
e (5.5 mM) and galactose (5.5 mM) inhibited
ansport of L-^{75}Se-methionine by 22% and 24%,
Ouabain (10^{-6} M) reduced transport of
-methionine if present on the serosal side,
t on the mucosal side; this indicated that
ansport of L-^{75}Se-methionine is dependent
he Na pump. Phlorhizin (10^{-4} M) did not af-
he transport of L-^{75}Se-methionine but did
duce the inhibitory effect of hexoses. The
l-to-serosal flux of L-^{75}Se-methionine ap-
ly requires an aerobic pathway involving oxi-
phosphorylation, since 2,4-dinitrophenol
M) and KCN (10^{-3} M) reduced the transport of
-methionine by 75% and 67%, resp. DL-Seleno-
nine (10 mM) reduced the rate of active
ort of ^{14}C-DL-methionine (1 mM), the corres-
g S-analog by 78%; this suggests that seleno-
nine and methionine utilize the same trans-
ystem. The implication of the S-Se antagon-
relation to active transport and Se poison-
e discussed.

INTESTINAL IRON ABSORPTION BY NEONATES
AND SOME FACTORS AFFECTING IT. (E.)
l, E. (Radcliffe Infirm., Oxford, England).
. Clin. Med. 70(1):138-149, 1967.

orption was studied in suckling rats (inbred
rats, Wistar strain) which were normal,
ransfused with viable RBC or overloaded
e, since it is known that their stores be-
elatively deficient in Fe while receiving
lk which is rich in Fe. A whole-body
ng technic was used with ^{59}Fe-labeled fer-
alts, hemoglobin and rat milk. Almost all
0 µg dose of Fe^{++} was absorbed during the
2 wk. of life; after this, absorption
lly declined to approx. 25% at 30 days of
^{59}Fe-labeled rat milk was absorbed in a
r manner, while ^{59}Fe-labeled hemoglobin was
ed less efficiently at all stages. Suckling
tal) rats resembled adults in that factors
d to the intestinal lumen, such as size of
dose and prior admin. of a large blocking
f Fe, reduced Fe^{++} absorption. They dif-
from adult rats in that factors which in-
intermediary Fe metabolism, such as the
of circulating RBC or the level of Fe stores,
t affect Fe^{++} absorption. These results
related to the observation that during the
first 18 days of life the intestinal mucosa of the rat is able to absorb large molecules, such as protein antibody, by pinocytosis. Cortisone acetate, admin. s.c. to rats 8-10 days old, has been shown to mature the intestinal absorptive cells within 72 hr. so that pinocytosis no longer occurs. A group of 12 neonatal rats which had been treated with cortisone acetate (inj. i.m.; 0.06 mg/g) when 10-11 days old, absorbed a mean of 76.0 ± 8.22% of a test dose of Fe^{++} admin. 3 days later; this was significantly less than the mean percentage of Fe absorbed by their littermate controls (88.3 ± 3.64%).

8724 RE-EVALUATION OF RADIO-IODINATED TRIOLEIN AS A TEST FAT IN FAT ABSORPTION STUDIES. (E.) Sie, H. G. (U. Groningen, Netherlands), A. J. Valkema and F. J. Loomeijer. J. Lab. Clin. Med. 70(1):121-128, 1967.

The absorption of radio-iodinated triolein was compared to that of glyceryl-trioleate-^{14}C (which is physiologically identical with natural triolein) in rats (albino, Wistar strain). The latter were maintained on an unrestricted diet of ground commercial rat chow and 10% olive oil. There was no difference in the absorption of these 2 radioactive fats as determined by the radioactivity in the stool. The absorption of radio-iodinated triolein mixed with olive oil was 91.7 ± 7.6%, compared to 91.6 ± 9.8% for glyceryl-trioleate-^{14}C. In the stomach, small intestine, cecum and colon, and in stool, no deiodination of the radio-iodinated triolein was found. However, in the small intestinal wall and in the thoracic duct lymph, massive deiodination of the ^{131}I-labeled fat was present. These results suggest that deiodination of the radio-iodinated triolein occurs after it is absorbed in the gastrointestinal tract. Because of this it is concluded that radio-iodinated triolein can be used to substitute glyceryl-trioleate-^{14}C and natural triolein as a test fat in fat absorption studies in the rat if fecal radioactivity is taken as the index for fat absorption.

8725 METHIONINE TRANSFER ACROSS GOLDFISH INTESTINE ACCLIMATIZED TO DIFFERENT TEMPERATURES. (E.) Smith, M. W. (A. R. C. Inst. Animal Physiol., Cambridge, England). Experienta 23(7):548-549, 1967.

Goldfish were maintained in aerated water at 8°, 15°, 20°, 25° or 30°C for 2-3 wk.; after sacrifice, the anterior intestine was everted on a polythene-covered metal rod to form 2 sacs which were both filled with 100 µliter of bicarbonate-saline containing 5.5 mM glucose and 10 mM methionine. The everted sacs were suspended from open-ended cannulae in 15 ml of the same methionine-containing bicarbonate-saline gassed with a mixture of 95% O_2 and 5% CO_2. One sac was incubated at 30°C and the other at a temperature equal to the previous environmental temperature of the fish. Serosal transfer of methionine, measured at 30°C, fell as the acclimatization temperature was raised, showing that some regulation of methionine transport (transfer) occurred. When the incubation temperature was adjusted to be the same as the environmental temperature of the fish, the transfer of methionine rose with increasing temperature, showing that the regulatory mechanism did not compensate fully for the rise in environmental temperature. The ability of goldfish intestine to conc. methionine at its serosal surface when incubated at 30°C showed no dependence on the previous acclimatization temperature. Both fluid and methionine transfer were measured at 30°C using intestines taken from fish acclimatized to different temperatures; the transfer of fluid was reduced 5-fold and the methionine transfer 2-fold for a 22°C shift in the acclimatization temperature. Thus, the regulation of methionine transfer seemed to be concerned primarily with regulation of fluid (and therefore Na) transfer. When these results on methionine transfer were compared with previous estimations of methionine, free in the intestinal mucosa and in the extracted protein, it was found that all 3 levels increased by approx. the same proportion for the same shift in acclimatization temperature; this implied that the ability of the mucosal cell to conc. methionine determines its own incorporation into protein. It is postulated that in the goldfish intestinal mucosa, methionine may act in opposition to valine as a pacemaker for other processes involved in the metabolic regulation of cells exposed to different temperatures.

8726 ESTIMATION OF HUMAN CALCIUM ABSORPTION BY EXTERNAL RADIOISOTOPE COUNTING. (E.) Curtis, F. K. (VA Hosp., Seattle, Wash.), H. Fellows and C. Rich. J. Lab. Clin. Med. 69(6): 1036-1041, 1967.

A large vol. scintillation counter was used to measure fractional accumulation of ^{47}Ca in the human forearm after an i.v. and a later p.o. dose of radioisotope; the fractional absorption of p.o. Ca was calculated from this information and compared to the absorption determined from stool radioisotope recovery. In practice, the patient was given an i.v. dose of approx. 1 μc of ^{47}Ca in 1 ml of saline containing 0.1 mg of ^{40}Ca; 23 hr. after the i.v. inj., the count rate of the arm was measured, after which exactly 25 ml of the same soln. of ^{47}Ca, mixed with 200 mg of Ca as calcium gluconate and 75 ml water, was given p.o. The patient was fasted for at least 12 hr. before and 2 hr. after this p.o. dose. Coincident with the p.o. dose, the patient was given 500 mg of chromium sesquioxide in a gelatin capsule, and a stool collection started. The arm count was determined 25-50 hr. after the p.o. dose, and the stool collection continued for at least 5 days. In 16 studies on 14 patients (10 with no evident disorders of Ca metabolism or intestinal function, and 1 each with osteomalacia, steatorrhea, osteoporosis and hyperparathyroidism), there was good agreement between the 2 methods with a correlation coefficient of 0.94. It is concluded that external counting offers a convenient and precise method to determine fractional absorp of ^{47}Ca.

8727 A NEUTRAL SODIUM PUMP AND THE HEXOS TRANSFER POTENTIAL IN THE RAT SMALL INTESTINE. (E.) Barry, R. J. C. (U. Sheffie England), J. Eggenton and D. H. Smyth. J. Ph (London) 191(2):72P-73P, 1967.

8754 THE ROLE OF ANTRUM-PYLORUS-DUODENUM SYSTEM IN THE EXCRETION OF GASTRIC JUICE IN RATS. (Hun.) Dobi, S. (U. Debrecen Sch. Med., Hungary), A. Györffy, G. Mózsik and T. Jávor. Kiserl. Orvostud. 18(6):579-581, 1966.

Ligature of the pylorus in rats leads to accumulation of gastric juice in the stomach and subsequently to development of Shay's ulcers. Whether the ligature of the pylorus is specifically responsible for this phenomenon was investigated. The following operations were done on groups of starving Wistar rats: Ligature of the pylorus, ligature at the boundary, above the limit, and below the boundary of the antrum, resp., and antrectomy. The animals were sacrificed 24 hr. after the operation, the amount and acidity of the gastric juice determined, and the pathological changes on the stomach mucous membrane evaluated. The av. vol. of gastric juice excreted were 20.4, 15.0, 12.0, 18.0, 15.7, and 21.2 ml after ligature of the pylorus, ligature at the boundary, above the boundary, and below the corpus-antrum boundary, antrectomy, and ligature of the duodenum above the common bile duct, resp. The incidence of ulcers in the same groups of rats was 65.0, 62.5, 0, 60.0, 60.0, and 20.0%, resp. The acidity of the gastric juice accumulated after the ligatures varied between 60-70 and 100-110 (U not stated). The only exception was the duodenal ligature, after which the acidity varied between 10-20 and 40-50. Therefore, the incidence of ulcers decreased markedly in this group of rats. In addition to the ligature of the pylorus, other treatments resulting in the prevention of the penetration of the gastric juice into the intestinal tract also led to the development of Shay ulcers in rats. Since antrectomized rats accumulated gastric juice in their stomach and developed ulcers similar to those after ligature of the pylorus, it is evident that gastrin does not play any role in the induction of gastric juice secretion after ligature of the pylorus.

8755 INDIVIDUAL VARIATION IN SECRETORY CAPACITY OF GASTRIC ACID TO STIMULATION WITH SOLID FOOD AND WITH HISTAMINE. (E.) Rune, S. J. (Bispebjerg Hosp., Copenhagen). Clin. Sci. 32(3):443-452, 1967.

The indirect method of estimating the rate of acid secretion after ingestion of solid food (beefsteak and vegetables), by measuring the increase in base conc. in the blood, was applied to 22 persons representing a wide range of secretory capacities of gastric acid. Acid secretion was also estimated after a max. histamine (0.04 mg/kg/hr.) infusion test. The test meal caused a rise in the blood base conc. in 20 of 22 subjects; anacidity was present in 1 of 2 cases, who did not respond to the meal with an increase in base conc.; the second had significant hypoacidity (max. response to histamine was 2 mEq/hr.). The mean rate of aci secretion in the first hr. after a normal meal ranged from 0-56 mEq/hr., with a mean of 31 mEq as compared with a range from 0-59 mEq/hr. (mea 32 mEq/hr.) in acid output in the first hr. of max. histamine infusion test; the individual responses to the 2 stimulations were highly correlated. It is concluded that vagal excitation and gastrin release after ingestion of solid fo provoked max. response by the gastric parietal cell; thus the rate of acid secretion in the ea postprandial peroid depends mostly on the parie cell mass.

8756 GASTRIC MUCOSA SECRETION IN NORMAL CONDITIONS AND IN CASES OF INTESTINAL METAPLASIA. (HISTOCHEMICAL STUDIES). (It.) Gentileschi, E. (U. Rome), V. Speranza, A. Marciani, F. Carotenuto and N. Casale. Gazz Int. Med. Chir. 72(9):721-735, 1967.

The periodic acid-Schiff reaction according to Hotchkiss-MacManus, Alcian blue 8 GS according to Steedman, the Feulgen reaction, and metachromatic staining with Blue A at pH 1 and 3 were the staining methods used. In normal gastric mucosa from 10 surgical patients, the epithelial cells of the upper portion of the gastric fossae stained more intensely with periodic acid-Schiff than those of the lower portion; epithelial cells of the lower portion stained more intensely with Alcian blue than those of the upper portion; metachromasia was observed only in epithelial cells of the lower portion at pH 3 and not at all at pH 1. Mucous cells of the neck of the fundus stained weakly with periodic acid-Schiff and Alcian blue but showed no metachromasia at pH of 3 or 1. Mucou cells of the antral region stained moderately with periodic acid-Schiff but not at all with the other stains. In gastric mucosa of gastric ulcer patients with intestinal metaplasia, goblet cells were scattered among epithelial cells which had lost their mucous activity. These goblet cells stained intensely with periodic acid-Schiff, Alcian blue, and metachromatic staining at pH 3.0; no metachromasia was observed at pH 1.0. Results indicate a predominance of mucoprotein in the secretion o normal gastric mucosa in contrast to a reductio in the number of mucous-secreting cells and a high percentage of acid mucopolysaccharides in the secretion of gastric mucosa undergoing intestinal metaplasia.

8757 THE USE OF INSULIN IN ANALYZING GASTRIC SECRETION. (Rus.) Arabadzhian, V. A. (Med. Inst. Stomatol., Moscow). Sovet. Med. 29(12):84-87, 1966.

Pronounced symptoms of hypoglycemia did not occur in any of 80 patients (duodenal ulcers in 45, gastric ulcers in 11 and chronic gastritis in 24) after inj. of insulin (12 U, admin. s.c.

evacuation of total gastric content). and caffeine stimulants did not provoke cid secretion in 24 patients, insulin ed anacidity in 10 while 14 had normal y. Anacidity was diagnosed by the Boas-test in 10 patients, and was verified by sulin test in only 2. Of 14 showing no cid secretion on a caffeine breakfast, 6 free acid (conc. was normal at times) insulin. Such differences were less pro- d in peptic ulcer patients, i.e., free n conc. more than 40 titer U upon insulin ation occurred in 39 patients, and by the wald and caffeine breakfast in 34; in 6, ee acid indices ranged from 104-120 titer duodenal ulcer cases the free HCl content rkedly higher (27) than in gas-ric ulcer (10) both on an empty stomach and during itial 30-min. of study. Max. acid content 3 Groups was found at 90 min. In chronic tis and gastric ulcer, secretion was n but it was intermittent in duodenal ulcer. eatest amount of juice was found in al ulcer, was lower in gastric ulcer and in chronic gastritis. Max. secretion of c juice occurred 75 min. after insulin The absence of side effects and char- stics of high secretion recommend insulin timulant of gastric secretion, especially sons with a decreased stomach secretory on.

AUTOREGULATION OF THE ANTRAL PHASE OF GASTRIC SECRETION. (Ger.) Lick, R. F. nich, Germany), H. Endres, H. Welsch, t, W. Brückner and O. Beck. *Z. Gastroent.* 8-71, 1967.

emale Heidenhain-pouch dogs (19-21.5 kg) trum was catheterized on the forward wall he greater curvature at the same session. sal secretion was measured 6-8 wk. after ion in the stomach and pouch of each followed by a number of standard tests mine, insulin, etc.), to determine the ory limits of each animal. The antrum was uously perfused through a double-lumen er with buffer soln. having precisely- d pH values; these buffer soln. (1 for eparate perfusion) were phosphate buffers H of 7, 5, 4, and 3 and glycocoll-HCl s having pH of 2.6, 2.4, 2.2 and 2.0, for es; another series was run having identical ues but with meat extract (30 g/liter of) added. The double lumen catheter was o maintain uniform conc. in the antral and also maintain uniform vol. to avoid re changes on the antral walls. Each test actly 1 hr. long. The secretions were ed for the usual parameters; vol., mEq nd pepsin conc. according to standard s. Neutralization of the antrum through uous perfusion with buffer soln. of pH 7 a powerful stimulation of the antral of gastric secretion as measured by pouch ion. (The basal pouch secretion was below 1 ml vol., below 0.01 mEq HCl and 150 U pepsin/hr.). The pouch secretion rose to 22 ml, 1.3 mEq HCl and 6,900 U pepsin/hr. When the buffered perfusate contained meat extract, the pouch secretion rose to 36 ml, 2.1 mEq HCl and 11060 U pepsin/hr. The first increase represented the antral phase of secretion; the second rise was due to gastrin. As the pH of the perfusate was lowered there was relatively less antral secretion phase and relatively more stimulation by gastrin. At pH 4 of the perfusate, the pouch secretion was 11 ml, 0.8 mEq HCl, and 4500 U pepsin/hr. At pH 4 with meat extract, the pouch secretion was 20 ml, 1.53 mEq HCl, and 6500 U pepsin/hr. Perfusion at pH 3 drastically reduced secretion. At pH 2.6 with meat extract there was strong gastric induction of secretion; 7.2 ml 0.3 mEq HCl and 3000 U pepsin/hr. However, at pH 2.2 with meat extract, the secretion was only basal, i.e., the gastrin mechanism was blocked as confirmed by further perfusion experiments.

8759 AN IMPROVED TECHNIQUE OF PERFUSION OF THE STOMACH FOR THE STUDY OF GASTRIC SECRETION IN THE RAT. (E.) Pissidis, G. A. (U. Leeds, England) and C. G. Clark. *Gut* 8(2): 196-197, 1967.

A perfusion technic is described which was designed to eliminate acid level fluctuation in the rat stomach due to inadequate perfusion of the organ by the inlet cathether, and due to irregular evacuation caused by the large size of the gastric rumen. The method is based on saline perfusion of the anesthetized rat stomach followed by measurement of perfusate acidity. A small polythene catheter was introduced into the stomach of the anesthetized rat previously fed dextrose and water for 48 hr. by a duodenal incision distal to the pylorus. The catheter was fixed. Another tube (a tip from a malleable Mackintosh's cocaine spray tube) was introduced into the rumen by an incision in the dome, and tied near the juncture of the body and rumen so as to exclude as much of the rumen as possible. Inlet and outlet tubes were brought through counter incisions in the animal's flanks. The glandular portion of the stomach should not be touched. An air pump sends saline in a fine spray at 35°C, and at a rate of 3 ml/min., through the stomach. Ten to 20 min. of washing the stomach with the saline precedes actual collection of 10-min., 30 ml-samples in graduated glass test tubes. These samples are titrated against 0.001 N NaOH with phenolphthalein. With this method the coefficient of variation is almost always more than 20%.

8760 GASTRIC SECRETION AFTER SIMPLE HISTAMINE STIMULATION IN DIFFERENT MORPHOLOGIC CONDITIONS OF THE MUCOSA OF THE STOMACH. PART I. (Ger.) Kaess, H. (U. Clin. Heidelberg, Germany). *Klin. Wschr.* 45(3):140-144, 1967.

In 96 patients, 32 with a normal gastric mucosa, 12 having light superficial gastritis, 21 severe superficial gastritis, 13 gastritis with atrophy and 18 chronic atrophic gastritis, were each inj. with 0.5 mg of histamine the fractionated gastric juice collected, and a biopsy taken of the gastric mucosa of each subject. The fixed tissues were graded according to pathology: light superficial gastritis showed slightly increased infiltration of lymphocytes, plasmacytes and histiocytes above normal numbers; severe superficial gastritis had a more dense infiltration of lymphocytes and plasmacytes with the addition of polymorphonuclear leukocytes and degenerative changes of the outer epithelium, while new glandular development was normal. Gastritis with atrophy presented an inflammatory type of infiltration, degenerative changes in the surface epithelium, shortening of the necks of glands, partly replaced by an unspecific type of gland; the chronic atrophic form of gastritis was marked by a decrease of glandular parenchyma occurring mostly in the form of lobulated glands, a dedifferentiation of epithelial cells, a rapid metaplasia of goblet cells and increase of lymphatic tissue. There was no case of hypertrophic gastritis among these 96 patients. Tendencies observable from the results of histamine stimulation on gastric secretion compared to the types of gastric pathologies and other factors present are: vol. of gastric secretion decreased with increasing pathological severity; proportionately in the decreasing vol. the acid decreased more rapidly so that the alkaline primary secretion, although about the same in vol., seemed to increase. An upward tendency of age was evident in passing from the normal through light and severe superficial gastritis, gastritis with atrophy, to frank chronic atrophic gastritis. The wide range of acid secretion in the normal and in the pathological conditions limits the diagnostic suitability of this method, despite av. general tendencies.

8761 GASTRIC SECRETION AFTER ORDINARY AND AFTER MAXIMAL HISTAMINE STIMULATION. PART II.

(Ger.) Kaess, H. (U. Clin. Heidelberg, Germany) and E. Oeckinghaus. Klin. Wschr. 45(3): 144-148, 1967.

In 22 patients with normal gastric mucosa, 14 with light superficial gastritis, 31 with severe superficial gastritis, 17 with chronic gastritis with atrophy, and 10 with chronic atrophic gastritis, were treated exactly as the patients in the preceding abstract except that these received 2 histamine inj.; 1 of 0.01 mg/kg (the ordinary dosage) and the other of 0.03 mg/kg (the max. dosage); each inj. was preceded by a basal collection of gastric juice and followed by fractionated collection of stimulated secretion. Again vol. and acidity were measured and the acid and alkaline secretions determined. Gastric mucosa histology was studied in each case and all possible correlations were made between secretions following ordinary and max. dosages of histamine and those of pathological states.
Acid secretion decreased progressively with
increasing severity of gastric mucosal atroph
Acid in mEq/liter/30 min. increased for the
of 22 normal subjects from 6.3 (lower dosage)
9.3 (max. dosage) or an increase of 48%. The
av. of 10 with chronic atrophic gastritis (l
dosage was 1.5 and at the max. dosage 2.3 (a
increase of 54%). Thus there was no impairme
of response of the remaining acid-secreting
cells in the pathological conditions. This
the fact that again the spread of values in
different pathological states was so great s
that no diagnostic importance could be attac
to the av. values or general tendencies obse
These variations were ascribed to neurohumor
influences in various morphologic states of
mucosa. There was no proportionality betwee
submax. and max. stimulation from case to ca

8762 EFFECT OF GASTRIN ON THE RELEASE O GASTRIC FLUID INTO THE DUODENUM IN RAT.

(Fr.) Vasseur, B. (Fac. Med., Paris),
J. Moline, P. Waltzing and P. Harichaux. C.
Soc. Biol. (Paris) 160(11):2192-2195, 1966.

To study the effect of gastrin on the motor
activity of the pylorus, independent of gast
acid activity, the esophagus was intubated a
the duodenum cannulated toward the pylorus i
anesthetized rats permitting the filling of
stomach with physiological saline at moderat
and constant pressure. Electronic transduce
registered the number of openings of the pyl
min. and the number of drops of fluid passin
from the stomach to the intestine. The acid
production of the stomach, induced by like
dosages of gastrin, was measured in control
animals. Gastrin was extracted from the pyl
mucosa of the hog; the standard extract con-
tained 1.5 mg of protein derived from 1 g of
fresh tissue; the upper limit of dosage was
about 50 mg/kg body wt.; the extract had no
contractile activity on the isolated ileum o
the guinea pig, thus excluding the presence
histamine. Extracts were also prepared from
human pyloric mucosa obtained at operation.
All extracts were dilated in distilled water
and inj. i.v. in vol. from 0.2-1.0 ml. The
rapid i.v. admin. of the extract caused a vo
reduction of the release from the pylorus
appearing during the min. following the end
inj. The reduction of the fluid flow varied
from case to case, from complete arrest for
about a min. to a reduction in the number of
drops over 2-3 min. The opening frequency o
the pylorus did not seem to be modified whil
further observation over a period of at leas
min. did not reveal any other motor effect.
the dose of gastrin was reduced the effect o
the vol. flow decreased and tended toward no
The i.v. inj. of physiological saline had no
effect on rate of pyloric opening or on the
of gastric juice passed into the duodenum.
Inj. of a stable ester of choline, carbamin
choline (0.2-1 μg/animal) reproduced faithf
the effect of the extracts upon pyloric mobi
and vol. flow. Slow admin. i.v. of the extr

loric mucosa failed to produce any change
normal. These effects were independent of
cid production of the stomach because no
e in the pH of the physiological saline in
tomach was noted for the duration of the

ISOLATION OF A CARRIER OF VITAMIN B_{12}
IN THE GASTRIC MUCOSA OF THE HOG.
Carlier, A. (City Hosp., Lille, Nord,
e), C. Boulanger, R. Havez and G. Biserte.
Acad. Sci. [D] (Paris) 264(18):2240-2243,

tract in 2% NaCl of the pyloric mucosa of
og was fractionated with $(NH_4)_2 SO_4$ after
uction of pepsin at pH 9.0. An auto-
graph was prepared by addition of $^{60}CoB_{12}$,
removal of excess free cyancobalamine by chromatography; the protein vitamin B_{12} complex was found in the region of the β globulins. Rabbit immunoserum was prepared from this material; immunoelectrophoresis of the proteins of hog serum mixed with the protein vitamin B complex differentiated the protein of the pyloric mucosa from all others. The protein itself was further conc. on a Sephadex column and proved to be homogeneous on electrophoresis on agar; this material seemed identical with the protein of the complex. High voltage electrophoresis finally separated it into 4 close fractions, the fourth of these was the carrier of the cyancobalamine. Thirteen mg of this fraction were obtained by the high voltage electrophoresis method. The molecular wt. of this substance was the lowest (among the protein substances) in the mucosal extract. The approx. molecular wt. (obtained by ultracentrifugation) was 4395±215 and is much smaller than that reported by others for the intrinsic factor of the hog. Nevertheless this preparation possesses the proper affinity for union with B_{12} and still preserves the specific antigenic determinant of hog intrinsic factor.

8765 A NEW ENZYME IN HUMAN GASTRIC JUICE. IMMUNOLOGIC, ELECTROPHORETIC AND ENZYMATIC PROPERTIES OF A CARBOXYLIC ESTERASE LOCATED IN THE GASTRIC MUCOSA WITH THE CAPACITY TO BIND VITAMIN B_{12}. (Ger.) Rapp, W. (U. Clin. Heidelberg, Germany). Klin. Wschr. 45(10): 533-541, 1967.

The normalcy of the gastric juice from 20 normal donors was determined from amount, pH, titration of free and bound acid, total wt. of pepsin, electrophoretic determination of pepsin, total protein, and, in 7 cases, histologic studies. Different gastric fractions were obtained: fasting, basal, and histamine-induced. The gastric juice was centrifuged to eliminate mucin; the supernatant (gastric juice) was cooled to 4°C and part of this juice lyophilized at pH 6.0-6.5. Postoperative human gastric mucosa was obtained and extracted. Gastric juice and mucosal extract each underwent electrophoretic separation and pepsin was removed from the gastric juice. Immunoelectrophoretic analysis and Ouchterlony preparations followed, allowing semi-quantitative determination of the esterase as an antigen. Through several stages of immune sera (prepared in the rabbit) to the use of the monospecific antiserum against the gastric juice esterase, successively purer preparations were made. Monospecific fluorescent antibodies (Coons) showed the intracellular presence of the enzyme in sections of frozen human gastric mucosa. This carboxylic esterase was found in the microsomal fraction of the fundic mucosa. The electrophoretic mobility corresponded to the β-1/γ-Ig G region in agar-gel electrophoresis at pH 8.2. This enzyme is a glycoprotein with excellent antigenic properties. The identity of this secreted antigen with the previously described antigen VIA has been proven by immunologic and biochemical methods. This antigenic enzyme can bind Vitamin B_{12} and corresponds to the slow vitamin B_{12} binder in gastric juice. The relationship to the intrinsic factor is almost certain. There are far-reaching biochemical reactivities identical for the human intrinsic factor and this carboxylic esterase. The 2 occupy identical positions in the chromatogram; the same positions chromatographically are occupied by a Vitamin B_{12} transfer factor, the intrinsic factor, and the autoantigen in pernicious anemia patients. A significant diminution of this esterase in pernicious anemia, gastric carcinoma and mucosal atrophy was observed in preliminary studies. As an enzyme it has a pH optimum of 6.6. Using β-naphthylacetate as substrate (1.075 mM) the reaction was linear; 20% of the substrate was converted in 3-10 min. Ca is apparently required for activation.

8766 EXCRETION OF PARENTERALLY ADMINISTERED LABELED VITAMIN B_{12} INTO THE RAT SMALL INTESTINE. (Hun.) Romics, L. (Budapest Med. U.) and M. Stützel. Kiserl. Orvostud. 19(1):48-54, 1967.

Vitamin B_{12}-Co^{58} (120 ng; specific activity 2 mc/mg) was inoc. into the tail vein of 3 groups of starving white rats. The second Group received the labeled vitamin after ligature of the common bile duct. In addition to this ligature, partial pancreatectomy was done on the third group before vitamin admin. All operations and inj. were carried out under narcosis (i.p. admin. of hexobarbital). The animals were sacrificed 1 and 24 hr. after vitamin admin., resp. After 24 hr. the kidneys and the collected urine, contained an av. 27%, the liver 7%, and the stomach, intestinal tract, and collected feces 15% of the input radioactivity. Distribution of the isotope did not change after ligature of the common bile duct or partial pancreatectomy. The bulk of the activity of the gastrointestinal tract was in the intestinal tract, where it was evenly distributed between the intestinal wall and the lumen. Ligature of the common bile duct or partial pancreatectomy did not change this pattern. Similar results occurred when the isotope distribution was investigated 1 hr. after labeled vitamin admin. The vitamin is excreted through the intestinal wall into the lumen. This process seems to be an active secretion, because admin. of 500 µg of cold vitamin B_{12} into the jejunum failed to inhibit the penetration of the label into the intestine and to affect its distribution between the intestinal wall and the intestinal content. Paper chromatography indicated that the radioactive compound in the intestinal tract was labeled vitamin B_{12}, rather than its degradation product.

8767 INTRINSIC-FACTOR SECRETION IN RESPONSE TO PENTAGASTRIN. (E.) Shearman, D. J. C. (U. Edinburgh, Scotland), N. D. C. Finlayson, I. M. Murray-Lyon, R. R. Samson and R. H. Girdwood. Lancet 2(7508):192-194, 1967.

In 15 patients with a variety of disorders, synthetic pentapeptide, pentagastrin (6 µg/k admin. s.c. or 6 µg/kg/hr., admin. i.v.), pr duced a similar gastric acid response as aug mented histamine (0.04 mg/kg s.c. or 0.04 mg/kg/hr., i.v.) stimulation. In 15 patient (7 of whom were achlorhydric) preliminary re suggested that these drugs also produce simi amounts of intrinsic factor. Patients were selected to cover the acid range 0-49 mEq. 1 patient complained of nausea in response t pentagastrin in contrast to 8 patients who h striking flushing and/or headache with hista It is concluded that, due to infrequency of side-effects, pentagastrin may be the stimul of choice in anemia or cardiovascular disord in the aged. This infrequency of side-effec also suggests the possibility of its increas ing the efficacy of screening tests for achlorhydria using Azure-A ion-exchange resi

8768 COMPARATIVE STUDY OF THE MODE OF STIMULATION OF INTRINSIC FACTOR. Tura, S. (U. Bologna, Italy), F. Possati, E. Fiore and L. Lodi. Boll. Soc. Ital. Biol Sper. 43(3):159-160, 1967.

The effects of histamine (0.02 mg/kg), betaz hydrochloride (1 mg/kg), and a mixture of am acids obtained by enzymatic breakdown of gel (450 mg) on acid secretion and intrinsic fac production were studied in 15 subjects with radiological, functional, or biopsy evidence gastrointestinal pathology. Two of the agen were admin. parenterally. Intrinsic factor determined by the radioimmune method. Gastr juice was collected over a 1-hr. period. Ac and intrinsic factor conc. was 19.47 mEq/hr. 7521 U, resp., with a correlation coefficien 0.77, after betazole; 15.2 mEq/hr. and 6205 resp., with a correlation coefficient of 0.8 after histamine; 7.9 mEq/hr. and 5424 U, res with a correlation coefficient of 0.76, afte amino acid mixture. Results indicate greate acid and intrinsic factor production followi histamine and betazole admin. than after a m ture of amino acids. Histamine causes less and intrinsic factor production than does be the difference between the 2 being statistic significant. An elevated correlation coeffi between acid and intrinsic factor production existed for all 3 agents.

8769 COMBINED ACTION OF ACETYLCHOLINE A HISTAMINE ON PEPSIN PRODUCTION IN STOMACH. (Rus.) Grechishkin, L. L. (Inst. Exper. Med., Leningrad, USSR). Farmakol. Toksik. 29(6):691-695, 1966.

Sensitivity of the chief cells (pepsin-formi of the gastric mucous membrane to acetylchol under the action of histamine (1 mg every 2

. s.c.) was studied in dogs (15-20 kg) with
ic fistulas. In 5 dogs treated with acetyl-
ne (15 μg/kg/min. for 80 min., admin. i.v.)
, the vol. of gastric juice/hr. during max.
tion varied between 15-42 ml, its pH was
.7; the pepsin conc. varied between 1.15-1.57
and the pepsin yield/hr. varied between
58.8 mg. In the same animals treated with
lcholine (15 μg/kg/min. for 60 min., admin.
and histamine, the resp. values were,
ic juice vol./hr., 145-165 ml, pH 1.3-1.55,
n conc. 1.00-1.48 mg/ml, and pepsin yield/hr.,
-244.2 mg. In 5 dogs treated with acetyl-
ne (1 μg/kg/min. for 60 min., admin. i.v.),
ic secretion was absent in 3 and only a
amount of mucus was secreted in 2; mucus
was 1.0 or 2.0 ml, pH was 6.0-7.5, pepsin
0.1-0.2 mg/ml, and pepsin yield/hr. was
.4 mg, resp. In the same dogs treated with
lcholine in a small dose and histamine,
ic juice vol./hr. varied between 115-180 ml,
tween 1.35-1.50, pepsin conc. between
0.64 mg/ml and pepsin yield/hr. between
95.3 mg. Pepsin yield, as found under
ic experimental conditions (in 2 dogs) with
min. of acetylcholine (1 μg/kg/min.) by
nged arterial infusion into the brain, did
xceed that after i.v. admin. of acetylcholine
e same dose, i.e., the av. pepsin yield/6
iments after i.v. admin. was 76.0 mg, and
intra-arterial admin. it was 70.6 mg.
fore, the potentiating effect of histamine
psin yield was not stimulated after intra-
ial admin. of acetylcholine; this indicates
the potentiating action of histamine occurs
e gastric wall periphery i.e., where histamine
f yields a secretory effect. Histamine, in
dmin. doses, did not depress the ability of
hief cells to yield pepsin.

THE LABELING OF PEPSIN BY ^{51}CrCl$_3$.
CHOICE OF TECHNICAL CONDITIONS AND
OLS. (Fr.) Cohen, Y. (Bichat Hosp., Paris),
anchard-Pelletier and S. Bonfils. C. R.
Biol. (Paris) 160(12):2272-2276, 1966.

echnic of marking pepsin with ^{51}CrCl$_3$ is
ibed. Material included: a 1% freshly
red soln. of twice-crystallized pepsin and
n. of ^{51}CrCl$_3$ of more than 2 mc/ml diluted
a soln. of CrCl$_3$ to contain a final titer
μg/ml of Cr. Marking the pepsin included:
of pepsin soln. and 200 μc of ^{51}CrCl$_2$ are
for 45 min at 37°C. Method of study of
arking included: Electrophoresis on paper
rious pH (6.9, 5.5, 1.6, 1.2, different
rs), 3 volts/cm^2 4-6 hr.; ninhydrin reaction
ach amide; another part of paper in contact
Kodirex film; electrophoresis in gelatin
combined with autoradiography using a pepsin
ence standard; purification of the marked
n by removal of all radioactive isotope not
by the enzyme through (a) mixing with
(Dowex) recovering supernatant and wash-
(b) dialysis through cellophane (Nojax 26)
of soln. against 50 ml H$_2$O at 4°C for 24 hr.,
or (c) chromatography on column of Sephadex G-25 20 cm long and 2 cm diameter; elution fluid, pH 6.0; 0.5 ml fractions. An alternate method with the column is given. Results: electrophoresis on paper; pH 6.9, 1 radioactive band at the anode; pH 5.5, 1 radioactive band at anode 1 band not radioactive at cathode; no migration at pH 1.6; at pH 1.2, 1 radioactive band at the anode. Electrophoresis in gelatin with reference standard showed peptic activity, not impaired by marking. The separation on the Sephadex G-25 column proved to be the most efficient.

8771 COMPARATIVE HISTOCHEMICAL STUDIES ON THE EPITHELIAL SECRETION OF THE GALL-BLADDER IN VERTEBRATES. (Fr.) Oledzka-Slotwinska, H. (Inst. Histol. Embryol., Acad. Med., Szczecin, Poland). C. R. Ass. Anat. 51(136):951-955, 1967.

Of 9 species studied, the amount of secretion in the frog, snake, and turkey was very small. In all species a complex mucoprotein was present; the protein portion gave a faintly positive Millon test. Secretion in animals with weak mucopolysaccharide reactions did not show strong protein reactions. The saccharide portion of the mucoprotein is probably a fucomucin while the acid radicals of the mucopolysaccharides are sulfuric and carboxylic. In the salamander, frog, snake and turkey, mucopolysaccharides with carboxyl groups predominate whereas in the tortoise, goose, dog, cat and man the sulfuric groups are chiefly present. The presence of chondroitin sulfuric acids A and C in the mucopolysaccharides of the secretions examined is doubtful. A principal source of the sulfuric radical seems to be heparin monosulfate. Sialic acid is the source of the carboxylic group.

8772 ACTION OF ATROPINE ON PANCREATIC AND BILIARY SECRETIONS IN THE RAT. CHOLERETIC EFFECT. (Fr.) Debray, C. (27 Rue Galilee, Paris), C. Vaille, J. De La Tour, C. Roze and M. Souchard. Gastroenterologia (Basel) 106(6):336-344, 1966.

Rats under urethane anesthesia were catheterized so that pancreatic juice and bile were separately and totally recovered. Temperature was maintained at 38 ± 0.5°C and respiration was recorded through changes in thoracic vol. After 6 hr. of observation and determination of basal secretory vol., the rats were inj. i.v., with atropine sulfate (30 mg/kg) and 15 min. later with a second dose of the same strength. These doses were much stronger than those in humans and dogs due to low sensitivity to this alkaloid. Bile production and the pancreatic juice were measured. The amplitude of respiration, the frequency, and their product, (amplitude frequency) were recorded. Results of groups of 10 rats receiving atropine were av., as were those of 10 control rats receiving appropriate saline inj. Results of biliary, but not pancreatic secretions, are recorded as net changes in vol., i.e., the subtraction of the vol. per unit time before the inj. from that after the inj. No significant decrease in pancreatic secretion was observed. During the course of the third hr. the vol. of pancreatic secretion increased rapidly compared to controls. Ten controls showed an av. of 3.40 (units not given) in the 3rd hr., and 10 rats with atropine in the same hr. av. 4.66 or 1.22 more, (36% more). In the previous hr. (second hr.) the experimental value was 28% more. Bile secretion in experimental animals increased about 46% in the first hr., 28% in the second and 10% in the third hr. (3 hr. av., 28%). In the same time, controls showed a total drop of 9%. Respiration in animals receiving 60 mg/kg of atropine sulfate was enhanced in an irregular manner; amplitude, and, generally, frequency were variable although above normal.

8773 COMPARISON OF THE ACTION OF MORPHINE, CODEINE AND NICOCODINE ON THE RESPIRATION AND THE EXTERNAL PANCREATIC AND BILIARY SECRETIONS OF THE RAT. (Fr.) Vaille, C. (Hosp. Bichat, Paris), C. Debray, J. De La Tour, C. Roze and M. Souchard. Arch. Int. Pharmacodyn. 167(1): 115-134, 1967.

Inj. of 0.01 and 0.02 g/kg of morphine HCl, 0.02 g/kg of codeine or 0.01 of 6-nicotinoylcodeine (Nicocodine) in male rats anesthetized with urethane for the performance of a double fistulization of the common bile duct demonstrated that these related drugs caused different pancreatic responses. Morphine, more than codeine, increased the flow of the pancreatic secretion while 6-nicotinoylcodeine had no effect. The amylase rate was slightly increased by morphine and codeine, while the total protein conc. was not significantly altered. Nicotinoylcodeine caused no changes. Morphine and nicotinoylcodeine did not alter the normal bile flow whereas codeine caused choleretic action for more than 1 hr. Choleresis was increased 40-50%, returning to normal within 2 hr. At the same time (with codeine) there was an initial decrease in bilirubin excretion during the hypercholeresis; it returned to normal and finally to slightly above normal. The bilirubin flow remained unchanged as the diminution of conc. was compensated by bile flow increase. Morphine and nicotinoylcodeine did not modify the excretion of bilirubin. The total enzyme flow (expressed by the conc. of proteins) was not significantly modified by any of these 3 drugs. At the conc. used, no mortalities occurred with either codeine or nicotinoylcodeine, but at the dose of 20 mg/kg of morphine, 5 of 11 rats died. All 3 depressed respiration: morphine more than codeine and codeine more than nicotinoylcodeine.

8774 SECRETORY FUNCTION OF THE STOMACH IN PARATHYROIDECTOMIZED RATS. (E.) Skatkov, M. E. (Inst. Norm. Path. Physiol., Moscow). Bull. Exp. Biol. Med. 62(11):1254-1255, 1966. [Transl. Biull. Eksp. Biol. Med. 62(11) 50-51, 1966.] Abstracted as GAC 2:5716.

8793 DETERMINATION OF THE IONIZATION CONSTANTS OF THE FUNCTIONAL GROUPS OF THE ACTIVE CENTER OF PEPSIN. (Rus.) Lutsenko, N. G. (Inst. Chem. Nat. Compounds, Moscow), L. M. Ginodman and V. N. Orekhovich. Biokhimiia 32(2): 223-227, 1967.

The kinetics of the enzymatic hydrolysis of 2 synthetic substrates of pepsin, N-acetyl-L-phenylalanyl-L-tyrosine and N-acetyl-L-phenylalanyl-L-tyrosine ethyl ether, at different conc. of substrates and at different pH values, was investigated and on the basis of experimental data, the pK values of functional groups of active enzymatic centers were determined. Values of the kinetic constants K_m and k_{+2} at different pH values (1.5-5.5) were obtained by investigation of the dependence of hydrolysis velocity on the substrate conc. (0.00025-0.005 M). Analysis of the dependence of lg k_{+2} and lg $\frac{k_{+2}}{k_m}$ on pH revealed the presence of a functional group with pK 3.0 in the active center of the free enzyme; the enzyme-substrate complex had a functional group with pK 3.8 (hydrolysis of N-acetyl-L-phenylalanyl-L-tyrosine) and with pK 4.2 (hydrolysis of N-acetyl-L-phenylalanyl-L-tyrosine ethyl ether). It can be assumed that the relatively low value of the pK group of the free enzyme is conditioned by its interaction with adjacent carboxyl groups. Upon formation of the enzyme-substrate complex, the interaction of the carboxyl groups is discontinued and the pK values acquired regular values characteristic for β- or γ-carboxyl groups of dicarbonic amino acids.

REFLEX AND ELECTROMYOGRAPHIC ABNORMAL-
ITIES ASSOCIATED WITH FECAL INCONTINENCE.
Alva, J. (Baltimore City Hosp., Md.), A. I.
eloff and M. M. Schuster. Gastroenterology
:101-106, 1967.

hnic is described for obtaining simultaneous
etric recordings of reflex responses from
internal and external anal sphincters along
electromyographic activity from the external
ncter. A total of 25 normal subjects were
ied and compared to 12 patients with gross
incontinence; 5 of the latter had intact
ilature but disrupted innervation due to
r complete transection of the lumbar spinal
or partial transection as a result of spinal
tumors; 2 had intact innervation but had
ary muscle disease and 5 patients had injury
al musculature secondary to surgical trauma.
combined technic showed that in the normal
ing state, the internal sphincter was strongly
racted and the external sphincter minimally
racted. Rectal distention produced a tran-
burst of increased activity beyond that
rved in resting muscle. The degree of in-
al sphincter relaxation and external sphincter
raction was directly proportional to the
ee of rectal distention. In patients with
incontinence, normal internal sphincter
exes were present, but external sphincter
exes were absent in incontinence regardless
e underlying cause, indicating that of the
scle components, the external sphincter plays
major role in the preservation of continence.
athy was demonstrated electromyographically
e external sphincter of patients who had

les.

STUDIES ON ANTISPASMODIC AND GENERAL
PHARMACOLOGICAL ACTIONS OF 3-BROMO-4-n-
XY-BENZOIC ACID DI-n-BUTYLAMINOETHYLAMIDE.
.) Kameyama, T. (Tohoku Coll. Pharm.,
ai, Japan) and K. Sasaki. Yakugaku Zasshi
Pharm. Soc. Jap.) 87(4):370-375, 1967.

spasmodic action was tested in 67 basic amides
alkamine esters using the excised intestine
ale mice in the Magnus method. In general,
e compounds had a strong papaverine-like
on; some of the basic amides showed atropine-
activity. One compound, 3-bromo-4-butoxy-
oic acid dibutylaminoethylamide, when tested
he Magnus method showed an antibarium chloride
on 3.94 times that of papavarine; its anti-
ylcholine activity was 0.0071 times that of
pine. This compound had a marked inhibitory
on on the contraction of rabbit intestine
ivo (Trendelenberg's method) in a conc. of
/kg body wt. inj. i.v. Acute toxicity of
omo-4-butoxybenzoic acid dibutylaminoethyl-
e was 218.5 mg/kg by s.c. inj. in mice.
tional extraintestinal responses are described.

8805 EFFECTS OF MORPHINE UPON THE ISOLATED SMALL INTESTINE OF RATS, RABBITS AND GUINEA PIGS. (E.) Hukuhara, T. (Okayama U. Med. Sch., Japan), H. Fukuda and T. Neya. Jap. J. Physiol. 16(5):528-540, 1966.

In most cases, morphine has an excitatory action upon the motility of the isolated small intestine of guinea pigs, rats and rabbits. The threshold conc. was found to be 10^{-10}, 10^{-7} and 10^{-6} g/ml, resp. At lesser conc. the contractions were increased in their amplitude with or without being accompanied with a rise of tone, while, at higher conc., there was a pronounced increase in tone which often culminated in its extreme to produce disordered contractions. With rats the admin. of the ganglionic blocking agent, nicotine (5×10^{-5} g/ml), along with morphine, produced a transitory inhibitory response 50 sec. later, which was followed by an excitatory response comparable to that obtained with morphine alone. This morphine excitation was not altered by the admin. of hexamethonium (5×10^{-4} g/ml) or atropine (10^{-4} g/ml). Furthermore, the admin. of morphine did not alter either the inhibitory response caused by the stimulation of mesenteric nerves nor the excitatory response produced by the admin. of a ganglionic stimulating agent, 1,1-dimethyl-4-phenyl-piperazinium iodide. These data suggest that the morphine excitatory effect on intestinal motility is due to its direct action on the muscle itself rather than by intramural nervous elements. Studies on the guinea pig and rabbit supported this conclusion.

8806 THE EFFECT OF STIMULATION OF THE HYPOTHALAMUS ON THE MOTOR ACTIVITY OF THE SMALL INTESTINE ON THE BASIS OF THE ACTIONS OF ACETYLCHOLINE AND EPINEPHRINE. (Uk.) Koval, L. O. (Shevchenko Inst. Physiol., Kiev, USSR). Fiziol. Zh. (Kiev) 13(2):244-256, 1967.

In a chronic experiment on fasted dogs (4) with electrodes implanted in the hypothalamus and equipped with small intestine fistulas, the action of electric stimulation (0.1-0.5 milliamperes, 50 hertz) of different parts of the hypothalamus on the motor activity of the small intestine was studied before and after the s.c. admin. of acetylcholine (0.2-1.5 mg/kg) or the i.v. admin. of epinephrine (0.005-0.02 mg/kg). Acetylcholine (1.0-1.5 mg/kg) always provoked or increased the motor activity of the small intestine. In a dose of 0.2-0.5 mg/kg, the action of acetylcholine on motor activity of the small intestine was dependent upon the functional status of the latter, i.e., during the first 3-5 min. of the resting period, the intestinal motor activity remained unchanged; if admin. later in the resting period, a local motor reaction occurred and it was increased. Admin. of acetylcholine during the period of intestinal action increased its contractions, with an increase in tonus.

Acetylcholine, given during the active intestinal period immediately after increase in motor activity (3-6 min. duration), caused motor activity to decrease to initial values or even caused slight inhibition. The action of epinephrine on the motor activity was also dependent on the functional status of the intestine. The strongest inhibition of the intestinal contractions was obtained after admin. of epinephrine at the start of the active period. After the inhibitory phase, stimulation of the intestinal motor activity was often observed. Admin. of epinephrine during the resting period could result in a stimulation phase, which sometimes lapsed into the active intestinal period. Stimulation of the anterior and central parts of the hypothalamus (0.1-0.3 milliamperes) during the state of rest or low contractions of the small intestine caused stimulation of motor activity and an increase in intestinal tonus (here, also, functional status of the intestine was of importance), while stimulation of the posterior part of the hypothalamus resulted in stimulation with a somewhat increased latent period. Stimulation of the anterior and central parts of the hypothalamus, at the time of stimulation of motor activity provoked by acetylcholine (Phase 1) or epinephrine (Phase 2) caused even greater motor activity in the intestine than without these substances. Low stimulation of the hypothalamus in the first 3-6 min. after initiation of the rest period did not cause stimulation of motor activity. Stimulation of the hypothalamus (0.1-0.2 milliamperes) at the time of Phase 2 of acetylcholine action had slight or no stimulatory effect; stimulation at points close to the mammillary bodies could have either stimulatory or inhibitory effects. Stimulation of the anterior and central parts of the hypothalamus under the inhibitory action of epinephrine had no effect on intestinal motor activity. Stimulation of the hypothalamus at the moment when Phase 2 of epinephrine action developed, or at the time when it usually developed, caused a greater degree of motor activity in the small intestine than without preliminary admin. of acetylcholine or epinephrine.

8807 CHRONIC IN SITU STUDIES OF THE ELECTRICAL ACTIVITY OF THE SMALL INTESTINE. (E.) Bunker, C. E. (Stanford U. Sch. Med., Palo Alto, Calif.), L. P. Johnson and T. S. Nelsen. Arch. Surg. (Chicago) 95(2):259-268, 1967.

Long-term, chronic in situ studies of the slow-wave electrical activity of the canine small intestine were performed on alert, unanesthetized dogs. The slow waves in the intact animal were stable under a variety of conditions for prolonged tests. After standard testing, surgical procedures performed on several dogs included bilateral transthoracic vagotomy, complete transection and immediate reanastomosis of the third portion of the duodenum, complete transection and immediate reanastomosis of the duodenal bulb, construction of Thiry fistulae from the third portion of duodenum and proximal jejunum and dissection of all tissue attached to the duodenal bulb. Mean slow-wave frequency was measured at all levels of the small intestin and the frequency defined; slow-wave frequencies of approx. 19 cycles/min. were usually found proximally, decreasing to 13-14 cycles/min. in the terminal ileum; this fall-off did not begin until well down into the mid-jejunum at a level of 75-90-cm from the ligament of Treitz. The normal frequency gradient was drastically altere by transection of the small intestine distal to the second portion of the duodenum, supporting the concept of a pacemaking area in this region. In the animal in which Thiry loops were construc from segments of duodenum and jejunum, all frequencies distal to the most cephalad anastomo (in midduodenum) were statistically the same and equal to those in the terminal ileum; also, mear slow-wave frequencies in the 2 isolated loops themselves were also at this same rate of approx 13 cycles/min., considerably different from thei preoperative values of approx. 19 cycles/min. I.v. admin. of 1 ml of a 1:1000 soln. of epinephrine produced striking increases in slow-wav rates. S.c. epinephrine in doses of 0.5-1.0 ml of the 1:1000 soln. produced no significant alte tions in frequencies. After rapid i.v. inj. of 1.2 mg of atropine, there was a slight fall in frequencies occurring soon after inj. and lastin over 1 hr. Vagotomy done in 1 animal produced results quite similar to that of atropinization, i.e., a fall in frequency of approx. 1 cycle/mi in the cephalad electrodes. In all animals, the admin. of i.v. insulin did not significantly alt slow-wave frequencies from fasting control value in general, feeding a standard amount of a commerical dog food preparation also had no effect mean frequencies, with a few exceptions. During occasional individual tests, a transient fall of approx. 1.0 cycle/min. was seen immediately afte feeding and lasted 5-10 min.; however, frequenci then returned promptly to fasting levels for the remaining 1-2 hr. of the tests, so that mean val for the entire postprandial period were unchange It is suggested that small intestinal smooth mus has a basic intrinsic rate of slow-wave activity which is much slower than that found in most of intact intestine distal to the second portion of the duodenum. The observed frequencies and grad ient in the intact intestine is presumably due t the action of a pacemaking area situated at or n the ampulla of Vater. The gradient can be viewe as (resulting from) a series of loosely coupled relaxation oscillators whose effect is conducte by the muscle itself. The degree of coupling to the proximal, faster activity is diminished with distance, thus accounting for the decreasing gradient of frequencies. Transection distal to the second portion of the duodenum interrupts communication with the pacemaker.

8808 EFFECTS OF N,N'-DIPHENYLDICARBAMATE-1 DIMETHYLOL CYCLOPENTANE (CAMALON) ON THE GASTROINTESTINAL MOTILITY IN RABBIT. (E.) Shimamoto, K. (Kyoto U., Japan), H. Hikosaka an T. Kiba. Acta Sch. Med. Univ. Kioto 39(3):180-184, 1966.

asmolytic effect of Camalon was investigated
rabbit upon the isolated intestine and
and upon movement of the stomach and
r in situ. Movements of strips of ileum
erus, suspended in oxygenated Ringer-Locke
maintained at 37.5°C, were recorded on
paper; the drugs used were admin. in the
conc. were given as g/ml. Large rabbits
ntubated with a gastric tube and balloon
with water; the vol. of water was adjusted
e the max. gastric movement. Bladder move-
were recorded using a bladder catheter,
g the bladder with Ringer's soln. warmed
5°C; stomach and bladder movements were
ered by tambour; drugs for stomach and
r tests were admin. by ear vein. Camalon
sted against or compared to $BaCl_2$, acetyl-
e, physostigmine, vasopressin, atropine,
rine and epinephrine. Camalon exerted
ic effects in the isolated intestine;
tation of motility in low conc. (2 x 10^{-7}-
$^{-5}$); above 1 x 10^{-5} the motility was
lly or progressively depressed in both fre-
and amplitude. The high conc. of Camalon
sed the stimulating effects of acetylcholine
Cl_2 on intestinal motility. This also oc-
with the uterine tissue; in addition, the
of epinephrine was diminsihed. The relax-
ffect of Camalon (1-3 mg/kg) on the move-
of the stomach lasted for 20 min. or more.
elaxing effect was more marked when the
ents had been augmented by i.v. inj. of
stigmine or vasopressin. The same dose of
on depressed the spontaneous movements of the
er in frequency and amplitude.

INFLUENCE OF STIMULATION OF THE AMYGDALA
ON ALIMENTARY MOTOR CONDITIONED REFLEXES
TOGENESIS IN DOGS. (Rus.) Vavilova, N. M.
ov Physiol. Inst., Koltushi, USSR). Zh.
. Nerv. Deiat. Pavlov 17(2):240-248, 1967.

ffects of unilateral electrical stimulation
e amygdaloid complex and body on conditioned
xes were studied in 17 randomly-bred dogs
mo. old). Insertion of bipolar electrodes
the left amygdaloid was followed, 2 days
surgery, by stimulation, which was applied
0-15 days. Stimulation was done with im-
generator IG-10; the frequency was usually
rtz, duration of impulses, 0.5 msec., stim-
on strength, 0.5-15 volts and duration of
lation, 30-40 sec. Electrical stimulation
e amygdaloid in dogs of various ages caused
kedly pronounced complex of nutritional
entary) behavior (licking, salivation, mas-
ion) as well as orienting and olfactory
ions. The threshold of stimulation (at
characteristic behavior reactions occurred,
.5-1.0 volts, and was approx. the same dur-
ll growth periods. In 2 animals (6-7 mo.
with electrodes localized in the pyriform
us toward the front of the amygdaloid com-
the most characteristic reactions were
catory. In all groups of animals studied,
lation of the amygdaloid body alleviated
the earlier-produced motor food conditioned reflexes. Stimulation, which caused a defensive reaction, inhibited conditioned reflexes chiefly in older dogs. In 3-4 mo. old puppies, stimulation of the amygdaloid body (used on the base of a differential signal) released differentiation, and in 6-7 mo. old animals, the latter was preserved. In 2 animals with electrodes placed in the pyriform region, electrical stimulation produced positive reactions similar to those which appeared upon amygdaloid stimulation, although mastication reactions were more pronounced. Therefore, besides other functions of the amygdaloid body, it is one of the segments of the nutritional multistage center.

8810 ON THE RAT GASTRIC MOTILITY. (E.) Hukuhara, T. (Okayama U. Med. Sch., Japan) and T. Neya. Jap. J. Physiol. 16(5):497-508, 1966.

In vivo studies of the adult rat stomach showed that gastric peristalsis always started every 10 sec., seen as a ring of contractions which was projected through the root of the left gastric artery at right angles to the curved long axis of the stomach (termed the pacemaker area). The muscle in this area contracted almost synchronously: the ring of contraction slowly propagated towards the pylorus with a velocity of about 1 mm/sec. Bilateral section of the vagus and/or the splanchnic nerves did not alter the site of initiation of these peristaltic waves. In vitro studies of the stomach showed the appearance of similar peristaltic waves but, unexpectedly, the pacemaker shifted and the peristalsis started at the top of the pars proventricularis and swept downward as a wave band to the former pacemaker region. When studies were made on various stomach strips the frequency of contractions was greatest in the fundic strip, nearly as great in the pacemaker strip, lowest in the sphincter strip, while the body strip was between the latter two. The strips made from the upper stomach regions contracted with a regular rhythm, whereas those made from the lower regions contracted irregularly. When physostigmine was applied, the frequency of contractions was hardly increased in either the fundic or pacemaker strips and only slightly in the body, whereas the sphincter and pyloric strips were remarkably stimulated. In short, the pyloric and sphincter strips showed the lower tone superimposed with rhythmic contractions of great amplitude, while the pacemaker and body had a higher tonicity but rhythmic contraction of a smaller amplitude.

8811 THE CORTICAL LOCALIZATION OF AFFERENT VISCERAL FUNCTIONS AND THEIR CONNECTIONS WITH THE NONSPECIFIC BRAIN SYSTEMS. (Rus.) Tolmasskaia, E. S. (Psychiat. Res. Inst., Moscow). Zh. Vyssh. Nerv. Deiat. Pavlov 17(2):295-303, 1967.

In man (11 healthy persons), the potentials provoked during stimulation of skin and gastric mucosal receptors had a latent period from 75-100 msec., with an amplitude of phases up to 80-90 msec. According to the latent period, they could be related to secondary induced potentials, but their localization in the cortex was different. Upon stimulation of gastric mucosal receptors, the provoked potentials as well as the reaction of desynchronization, were localized in the precentral and frontal region of the cortex; upon stimulation of skin receptors, their localization was in the parietal and precentral regions. Therefore, both methods of registration demonstrated that in the human, visceral sensation is presented more forward in the cortex than the somatic sensation. It was also found that visceral sensation is bound to a greater degree with nonspecific systems of the brain than with specific systems. In a study on rabbits (122), cats (48) and rats (22), by stimulation of the splanchnic and sciatic nerves, it was found that the degree of demarcation of the localization of visceral and somatic sensation differs in various species of animals. In various animals, the degree of the participation of specific and nonspecific systems of the brain in the perception of visceral functions may be different.

8812 EFFECT OF SALIVA ON GASTRIC EMPTYING. (E.) Malhotra, S. L. (Western Railway Med. Dept., Bombay). Amer. J. Physiol. 213(1): 169-173, 1967.

The effect of saliva on gastric emptying of fluid meals was studied by serial test meals using the dye-dilution technic; the experiments were so designed that the saliva was added to the meal in 1 set of observations and excluded from the other. The meals consisted of the South Indian appetizer called rasam, marked with a known quantity of phenol red (1 mg/100 ml); the pH of the meal was adjusted to 4.6. Results based upon 196 serial test meals showed that gastric emptying was significantly retarded when saliva was added to the meals than when it was not. This effect may have been due to some factor or factors in the saliva which retard gastric emptying. As an example, the action may be mediated through the action of salivary amylase in the meal producing sucrose, which in turn may inhibit the process of gastric emptying; or the mucus in the saliva may be precipitated on the gastric mucosa and in this state might be less permeable to stimuli responsible for gastric peristalsis, which are thus prevented from reaching the receptors, and in this manner may retard the gastric emptying rate.

8813 ENTEROGASTRONE INHIBITS EATING BY FASTED MICE. (E.) Schally, A. V. (Tulane U. Sch. Med., New Orleans, La.), T. W. Redding, H. W. Lucien and J. Meyer. Science 157(3785):210-211, 1967.

White Swiss female mice were fed a liquid diet consisting of 7.4% protein, 11.6% carbohydrate and 2.1% fat; they were then fasted for 17 hr., except that water was provided ad libitum to eliminate the effects of dehydration and thirst. The mice were then inj. i.v. or s.c. with test substances; controls were inj. with saline or carrier vehicle (which contained 16% gelatin and 0.5% phenol). Food was made available to the mic 10-15 min. later, and food consumption was measured after 30, 60, 120 and 240 min. A single inj. of enterogastrone (0.1-1.0 mg) purified from hog duodenum significantly reduced food-intake during the first 30-60 min.; there was no decrease in intake during later periods, but the cumulative changes remained evident after 4 hr. Two peptide preparations from hog duodenum (1 mg) had a slight effect when it was measured at 30 min., but the cumulative reduction was not observed between 1 and 4 hr. later; it is suggested that their minor effects may have been attributab to slight contamination with enterogastrone. Material purified from pig colonic mucosa (1 mg), as well as secretin (10 μg), glucagon (1 mg), bovine serum albumin (1 mg) and glucose (75 mg) had no effects. The anorexic agent chlorphentermine-HCl, admin. i.v. at 300 μg/mouse, significantly reduced intake during the first 30 min., and its cumulative effects were significant for as long as 2 hr. It is suggested that enterogastrone may be involved in inhibition of feeding it may act by inhibition of gastric contractions, and in part, humorally on the central nervous system.

8814 THE AMNIOGRAPH AS A METHOD OF STUDY OF GASTROINTESTINAL MOTILITY OF THE HUMAN FETUS in utero. ITS RELATION TO CHRONIC FETAL DISEASE. (Sp.) Karchmer K, S. (1st Gynec. Obstet. 8824 THE EFFECT OF ISOPRENALINE ON THE BILE SECRETION OF ANAESTHETIZED DOGS. (E.) Kasture, A. V. (Nagpur U., India) and A. K. Dorle. Curr. Sci. 36(7):178-179, 1967.

β-Isoproterenol was admin. i.v. to dogs with catheters of the bile duct in conc. of 0.01-10 μg/kg. Rate of bile secretion and conc. of bilirubin, bile acids, cholesterol and total solids were measured. β-Isoproterenol had a biphasic action on the vol. of secretion of bile, increasing it within the first 4 min., then decreasing it for 4-6 min.; for the 4 conc. of β-isoproterenol used, the increases were, resp., 27.2, 46.8, 81.2, and 163.5% and the decreases were, barely perceptible, 15.8, 34.4, and 63.3%. Analysis of the bile following i.v. inj. of 10 mg/kg showed increased bile acids (3.07 g/100 ml, normal 2.37 g/100 ml) and total solids (5.6 g/100 ml, normal 3.97 g/100 ml) and decreased cholesterol (41.9 mg/100 ml, normal 83.9 mg/100 ml), 4-6 min. after inj. The conc. of bilirubin was not significantly affected. The increase in bile acids with the concomitant decrease of cholesterol may have resulted from increased biosynthesis of bile acids from cholesterol in the liver.

8825 ACTION OF HYPOTHERMIA ON LIVER FUNCTION. (Fr.) Vanlerenberghe, J. (Fac. Med., Lille, France), N. Trupin-Bar, R. Guislain and C. Bel. J. Physiol. (Paris) 59(2):111-138, 1967.

The effect of lowered temperature on the vol. and conc. of constituents of bile was studied in white rats under anesthesia (normal temperature, 30°C and/or 25°C) with acute biliary fistula, or using the isolated perfused liver at temperatures, 40°, 30°, 25°, 20°, 15°, and 10° C or at some some of these decreased temperatures. The perfusion apparatus had a reservoir of the constant level type, 20 cm above the hepatic vein draining the excised liver, assuring constant pressure and rate of flow. Inflow was by way of the portal vein; temperature was closely maintained; the perfusate passed through a liquid film oxygenator supplied with pure, humidified O_2; the perfusate was part blood and part balanced physiological salt soln. The vol. of bile was measured directly in a graduated tube at 30-min. intervals. Total solids were determined after dessication. Bilirubin was assayed by spectrophotometry; Na and K by flame photometry; Cl by colorimetry; reducing sugars by 2 methods; bile salts were determined colorimetrically after separation by electrophoresis; BSP was determined photometrically as was D-xylose; radioactive iodine was measured by a scintillation counter. The changes in conc. were negligible for these substances during periods of hypothermia both in the whole animal and in the isolated perfused liver; the output of these substances followed changes in the liquid component. Hypothermia, like cyanide, did not upset the concentrating function of the hepatic parenchyma. These results are unlike those obtained with monoiodoacetic acid and phlorhizin. The Van't Hoff temperature coefficients remained between 2 and 3 for the temperature range 40°-10°C. The vol. reductions of bile with decrease temperature were about 50% at 30°C, 72% at 25°C, 89% at 20°C, 92% at 15°C and 95% at 10°C as compared to the vol. at 38°C.

8826 INDEPENDENCE OF HYPERPLASTIC AND HYPERTROPHIC RESPONSES IN LIVER REGENERATION. (E.) Sigel, B. (Woman's Med. Co Philadelphia, Pa.), L. B. Baldia, H. Menduke and Feigl. Surg. Gynec. Obstet. 125(1):95-100, 196

In dogs, partial hepatectomy and Eck fistula eac produced a cellular response in small, heterotopically-placed liver autografts; the graft effects of both of these procedures were differe Partial hepatectomy induced both hyperplasia and hypertrophy in the grafts. Eck fistula led main to hypertrophy without a concomitant hyperplasia Since both graft effects were probably mediated through a constitutent change in the blood, humo mechanisms were thought to be responsible for each effect. Hyperplasia and hypertrophy have been known to occur independently in the nontran planted liver. In the present experiments, it was shown that hypertrophy can be induced in grafts without hyperplasia. Thus, it was concl that 2 different humoral mechanisms were evoked after partial hepatectomy and Eck fistula, and that these were independent of each other. This deduction indicates that possibly different hepatic injuries lead to specific liver cell responses through humoral means. The regulation of liver regeneration may be by a series of humoral mechanisms which may, in the final analysis, represent the composite and expression of many biochemical feedback reactions.

8827 THE PREPARATION OF METABOLICALLY ACTI SUSPENSIONS OF MOUSE LIVER CELLS. (E Gardner, D. A. (U. Rochester Sch. Med., N. Y.) and E. R. M. Kay. Experientia 23(7):596-597, 1967.

A simple and rapid (35 min.) method for the isolation of free mouse-liver cells is describe this method minimizes the physical treatment to suspended cells once they are freed from the tissue. An adult CFW mouse is placed under ether anesthesia and the liver is perfused, in situ, through the portal vein with 15-20 ml of Ca-free Locke's soln. at room temperature at pH 7.3; perfusion is done slowly (1.5-2.0 min. to completion). Immediately after perfusion, the liver is excised and rinsed twice in Ca-free Locke's soln. at room temperature. To insure a sufficient number of cells for metabolic studie a second mouse liver is prepared in the same wa The combined livers are rapidly weighed and the cut into pieces of approx. 3 mm^3 size. The tis then dispersed very gently by pressing it with Teflon pestle through a sac made of hard finish cron mesh into a Thomas grinding vessel, size containing only 30 ml of Ca-free Locke's soln. room temperature. While the tissue is pressed ntly, the individual cells disperse into the lk of the suspension medium, thus avoiding any ditional contact between free cells and the stle. When most of the tissue (approx. 85%) s been dispersed, the suspension is filtered rough a filter of fine mesh rayon (80 threads/in. 84 threads/in.) to remove large clumps of lls; the suspended cells are gently sedimented centrifugation at 50 g for 4 min. at 4°C. e supernatant is removed by suction and the dimented cells are carefully resuspended in ml of Ca-free Locke's soln. using a pipette th an orifice of 0.09 mm, or larger. The cells e sedimented again for 3.5 min. at 50 g; after moval of the supernatant by suction, the cells e resuspended in 15 ml of Ca-free Locke's soln. was found that this method consistently gave yield of from 40-50% of the original tissue ss recovered as intact free cells. Two mouse ver cells dispersed in this manner yield 8-2.2 ml of packed cells which have a dry . of 160-200 mg; the number of cells in the spension was found repeatedly to be 35 x 10^6 ± % of cells/g of dispersed liver. It was found at the free cells maintained at 25°C in the sence of additional substrates (other than e 5.5 x 10^{-3} M glucose present in Ca-free cke's soln.) exhibited a slowly decreasing pacity to respire.

28 LIVER LIPOSOMES. I. ISOLATION AND CHEMICAL CHARACTERIZATION. (E.) hlunk, F. F. (U. Pittsburgh Sch. Med., Pa.) d B. Lombardi. Lab. Invest. 17(1):30-38, 1967.

ite female (Wistar strain) rats were given DL-hionine (as a 2.5% soln. in saline at a dosage l mg/g) by stomach tube in 2 equally divided ses at zero time and after 2 hr.; equal vol. of line were admin. similarly to controls. Hepatic posomes were isolated and purified by a method scribed in detail, after sacrifice and removal the rat livers. Liposomes (revealed by electron croscopic studies) are structures constituted osmiophilic centers enclosed by membranes, in e endoplasmic reticulum of liver and other cells gaged in active esterification of fatty acids. posomes isolated from livers of ethionine-eated rats appeared as spherical bodies ranging diameter from 1500-2500 Å; they were limited membranes and had contents of an electron nsity somewhat less than that of liposomes situ. The membranes were sometimes studded th ribosomes, but most often appeared to be ee of ribonucleoprotein. Chemical analyses of e contents of isolated liposomes showed them consist mainly of neutral lipids, chiefly iglycerides. The conc. of protein, phospholipid d RNA was highest in preparations of microsomes d liposome membranes, slightly lower in lipo-mes and least in preparations of liposome con-nts. The conc. of free cholesterol was con-derably higher than that of cholesterol esters all fractions, except liposome contents. The phospholipid and RNA contents of liposomes and microsomes from ethionine-treated and control rats, and of liposome membranes from ethionine-treated rats were very similar; phospholipid and RNA in preparations of liposome contents were quite low. The amount of triglycerides in the microsomal preparations from ethionine-treated and control animals and in the liposome membrane preparations from ethionine-treated rats was very low and quite similar. The triglyceride content was quite large in liposomes, especially in those obtained from livers of ethionine-treated rats, and in preparations of liposome contents which contained more than 3-times as much triglyceride as the liposomes obtained from the corresponding livers. Data supporting the view that liposome membranes derive from those of the endoplasmic reticulum are also presented, and the possible physiopathologic significance of liposomes is discussed.

8829 INFLUENCE OF ISOBARIC AND HYPERBARIC OXYGEN ON BILIARY PO_2 AND THE MECHANICS OF BILE FLOW. (E.) Kelly, K. A. (U. Amsterdam) and P. J. Klopper. Amer. J. Physiol. 212(5): 1017-1024, 1967.

Arterial, inferior vena caval, portal venous, and biliary PO_2 values were determined in rabbits breathing air, isobaric O_2, and hyperbaric O_2. Rate of bile flow, rate of rise of bile secreted into a vertical catheter, and max. biliary secretion pressure were also measured. When breathing isobaric air, the PO_2 in bile was always greater than that in the portal venous blood and was closer to the PO_2 in the arterial blood. Biliary PO_2 markedly increased when iso- and hyperbaric O_2 were admin., as did arterial but not portal venous PO_2. Bile flow, rate of rise of bile in a vertical catheter, and max. biliary secretion pressure were not significantly altered during the varied experimental conditions. An intimate contact between hepatic arterial blood and bile is suggested by the data.

8830 EFFECT OF ADMINISTRATION OF 3-AMINOTRIAZOLE ON THE ACTIVITY OF MICROSOMAL DRUG-METABOLIZING ENZYME SYSTEMS OF RAT LIVER. (E.) Kato, R. (Nat. Inst. Hyg. Sci., Tokyo). Jap. J. Pharmacol. 17(1):56-63, 1967.

Inj. of 3-aminotriazole (i.p. at 125-2000 mg/kg) to male rats markedly decreased the hexobarbital hydroxylation, aminopyrine N-demethylation, aniline hydroxylation and the p-nitrobenzoic acid nitro-reduction in the liver microsomes. Moreover, the content of P-450 (a microsomal CO-binding hemoprotein) was also decreased but the liver microsome content of cytochrome b_5 was not decreased. Furthermore, the admin. of 3-aminotriazole (500 mg/i.p.) significantly prevented the increase in the hexobarbital hydroxylation, aminopyrine N-demethylation and the p-nitrobenzoic acid nitro-reduction induced by the admin. of phenobarbital and methylcholanthrene. Studies showed that the admin. of 2000 mg/kg i.p. of 3-aminotriazole decreased the rate of pentobarbital metabolism in vivo by 37%. Addition of 3-aminotriazole only slightly inhibited the activity of the microsomal enzymes and the preincubation of the microsomes containing supernatant with 3-aminotriazole did not increase the inhibitory action of 3-aminotriazole. The results suggest that the decrease in the activities of drug-metaboling enzymes may be reflected by the change in the content of P-450, probably through the inhibition of biosynthesis of the P-450 moiety.

8831 PATHOPHYSIOLOGICAL STUDIES ON IRON METABOLISM. ACTIVITY OF IRON-FLAVIN ENZYMES AND CONTENTS OF IRON AND RIBOFLAVIN IN REGENERATING LIVER. (Jap.) Nakamura, S. (Kyushu U., Fukuoka, Japan). Igaku Kenkyu (Acta Med. [Fukuoka]) 36(2):219-238, 1966.

Three main groups of rats were studied: (1) animals maintained on a normal diet, (2) animals on a diet deficient in Fe, and (3) rats on a diet deficient in riboflavin. Each group was divided into an unoperated subgroup and a subgroup 40% hepatectomized. At 48 and 72 hr. after operation on the animals with normal diet and at 48 hr. in the deficient groups, the activities of succinic dehydrogenase, reduced diphosphopyridine nucleotide diaphorase (DPNH diaphorase), and xanthine oxidase were determined in regenerating liver tissue as well as in liver tissue from unoperated animals maintained on the normal and the deficient diets. Some tissue (equal wt.) from each subgroup was homogenized in 0.25 M sucrose and differentially centrifuged in a number of stages into mitochondrial and microsomal fractions and a final supernatant vol.; these 3 portions were then quantitatively tested for the activity of the 3 enzymes. The activity of succinic dehydrogenase was decreased in the unoperated livers of animals both in the Fe-deficient and riboflavin-deficient groups; following partial resection, the animals on a normal diet showed decreased succinic dehydrogenase activity at 48 hr. and slightly increased activity at 72 hr.; activity of the Fe-deficient group was increased at 48 hr. and activity of the riboflavin-deficient group was decreased. No difference was noted in activity of DPNH-diaphorase in mitochondria and in microsomes of unoperated normal diet and Fe-deficient groups; a slight decrease of DPNH-diaphorase activity was detected in the microsomes of the unoperated riboflavin-deficient group. The DPNH-diaphorase activity in mitochondria of regenerating liver (normal diet) was always more than normal at 48 hr. and increased at 72 hr., while that in the microsomes was doubled at 48 hr. and increased further at 72 hr. Xanthine oxidase activity was slightly decreased in the unoperated Fe-deficient liver and markedly depressed in the unoperated riboflavin-deficient organ; in regenerating liver, xanthine oxidase activity was greatly increased both in control (48 and 72 hr.) and in the deficient groups, although lower than in the control animals. In regenerating liver the content of non-hemin Fe was increased in the control rats and even in the Fe-deficient rat; the riboflavin content was elevated in the control group and even in the riboflavin-deficient group.

8832 HEPATIC DIURNAL CYCLE. (Fr.) Suppan P. (U. Lausanne, Switzerland). Acta Anat. (Basal) 65(4):584-593, 1967.

White male rats (200-300 g) were maintained on standard diet in a constant environment: 22°C and 55% humidity with daylight the only illumin tion. Four series of 24 animals each were used 1 series in each season of the yr. In each ser 2 rats were killed by decapitation every 2 hr.; pieces of the right lobe of the liver were prepared for histologic examination. For karyomet examination 500 nuclei were drawn 2300 times an then measured by planimetry. The size of nucle reached a max. in each 2-hr. cycle over a perio of 24 hr. During the daytime the nuclei were generally larger and their variability greater than during the night. These changes in size were statistically significant in 7 of 12 diurn periods of 2 hr. each. The daily changes were v similar during the 4 seasons of the yr. In the course of the daily cycle binuclear cells reach a peak at 10 PM and giant nuclei were max. at 6

8833 RELEASE OF LIPOPROTEIN LIPASE FROM TH PERFUSED LIVER OF THE RAT. (E.) Fel J. M. (Roy. Vet. Coll., London) and P. A. Mayes Nature (London) 214(5088):620-621, 1967.

Livers from 4 male rats were perfused with 100 whole, defibrinated rat blood. In 2 (Group 1), increasing conc. of heparin (0, 0.4, 4.0, 40, 200 I.U./mg), NaCl, and protamine sulfate were made to replicate incubations so that their con were 0.4 I.U./ml, 0.6 M and 0.3 mg/ml, resp. Lipase activity of perfusate increased significantly with time in Group 1, but not in Group 2 Addition of heparin to the assay system significantly stimulated lipase activity in serum from Group 2, but not from Group 1, where hepar had already activated lipoprotein lipase. Addi tion of NaCl to the assay system caused a significant inhibition of lipase activity in Group 1 (30, 45, 60 min.) and also when added to the heparin-activated Group 2. Addition of protami sulfate caused only a slight, but significant, inhibition of lipase activity when added to ser from Group 1 (30, 45, 60 min.), since the serum at those time intervals contained much heparin. Protamine sulfate also significantly inhibited lipase activity when added to the heparin-activ serum of Group 2. In a separate experiment, in creasing conc. of heparin were added to whole, defibrinated rat blood while circulating in the perfusion apparatus, but with no liver in the c cuit; it was shown that the liver was the sourc of the additional lipoprotein lipase found in t perfusate in Group 1. Addition of a large amou of heparin caused the liver to release a lipoly enzyme into the circulation, but this does not mean that lipoprotein lipase is functional in t liver. The results support the authors' previously expressed theory that the results of others on the metabolism of chylomicrons or triglycerides in the perfused liver, in which substantial rates of uptake and oxidation were fou were the consequence of the activation of lipoprotein by heparin.

DIAGNOSTIC PROCEDURES AND GENERAL THERAPY

)1 USE OF ULTRASOUND FOR PREPARATION OF A
HIGHLY DISPERSED SUSPENSION OF BARIUM
FATE. (Rus.) Petrov, V. I. (Moscow Region.
. Res. Clin. Inst.) and G. A. Onoprienko.
tn. Rentgen. Radiol. 42(1):27-32, 1967.

ighly-dispersed suspension of $BaSO_4$ was ob-
ned by ultrasonic means. The optimal condi-
ns of sound treatment are use of a magneto-
ictive radiator at a frequency of 20 kilohertz,
ensity of approx. 3-5 watt/cm^2 and a 20-min.
osure at 20°-25°; the presence of a stabilizer
latin in a ratio of 1:100 dry wt.) is essential.
ked diminution of the viscosity of the sus-
sion, which was obtained in the acoustic field
the presence of gelatin, allows a conc. of
O_4 of up to 70%; this significantly increases
contrast characteristics of the mass. After
nd treatment, all of the particles of $BaSO_4$
1µ or less in size. The suspension obtained
ffers by a high stability; marked precipitation
the particles began after 8-10 hr. The rela-
ely low viscosity (at conc. of 50-60%), the
h amount of dispersion and contrast of the
pension improves the mucosal picture during
ay examination of the gastrointestinal tract,
significantly improves diagnosis.

)2 SINGLE LAYERED SUTURES IN THE INTESTINE
(CLINICAL AND EXPERIMENTAL STUDIES).
r.) Marella, M. S. (Fac. Med., Montevideo)
A. Del Campo. *Zbl. Chir.* 92(18):633-636, 1967.

experimental series of operations (end-to-end
stomosis of the large intestine) in 39 dogs
undertaken to study and improve the suturing
the intestinal wall. Resections with end-to-
anastomoses (44), 29 resections of the colon
15 of the ileum and jejunum were done in man
ng these technics. Specific points stressed
the experimental series were: 1) Clamping of
intestine was avoided. 2) Atraumatic needles
nonabsorbable suture thread were used. 3)
eeding was carefully stopped by ligatures while
blood flow to the intestine was unimpeded.
The suturing of the far wall followed with tied
tures (2-3 mm apart in the dog, 3-4 mm in man)
luding the serosa, muscularis, and submucosa,
not the mucosa; the suture threads were tied
the intestinal lumen. 5) The suturing of the
r wall then proceeded in a similar manner.
rty dogs had single-layered and 9 double-
yered sutures. Linen or silk thread coated
th petroleum jelly were the materials used; nylon
ofilament was tried, but its lesser flexibility
de it difficult to tie triple knots, increasing
danger of ripping the wall; the formation
adhesions was also greater when nylon was
ed. Comparing the results of single-layered
double-layered sutures, the suture insuf-
ciency was the same; actually these insuf-
ciencies occurred during the first few cases
ly so that they may have been operational.
e single-layered sutures restored the continuity
of the intestine. These technics were followed in the 44 human resections. The end-to-end anastomoses using the single-layered sutures resulted in a lumen of larger diameter, and a suture roll thinner than in multilayered methods. Advantages of the single-layered sutures are: 1) The disruption of the blood supply is minimal; 2) No dead spaces are formed as in multilayers to collect exudate, become infected, and finally cause fistulas and stenosis; 3) The strength of the suture is dependent upon the individual technic, and the state of the surrounding tissue; the strength of the single-layered sutures themselves is more than adequate.

8903 RESULTS OF INVESTIGATIONS ON INTESTINAL BACTERIA IN THE FOOD INDUSTRY (WITH CONSIDERATION OF THE NEED FOR URINE EXAMINATIONS). (Ger.) Gärtner, H. (U. Kiel, Germany) and I. Böhlck. *Oeff. Gesundheitswesen* 29(5-6):266-271, 1967.

During the period 1962-1966 inclusive, 244,861 stool examinations were made of healthy persons engaged in the food industry in Schleswig-Holstein, ranging from 45,000 to 52,000/yr. with an av. of nearly 49,000/yr. Among these a total of 104 or 0.042% were positive for undesirable bacterial forms. Of these 27 had *Salmonella typhi*, and 25 *S. paratyphi* B; 50 had other lesser forms of *Salmonella* and 2 were carriers of *Shigella sonnei*. Repeated examinations of carriers showed that 35 of 88 investigated in the years 1963-1966 were long-term harborers. One carrier of *S. paratyphi* B was positive 19 times in stool and 11 times in urine examinations; following cholecystectomy and a course of penicillin therapy 11 stool and 17 urine examinations over a period of 1.5 yr. proved to be negative. In all cases none of these bacteria were found in the urine unless they were also present in the feces. The urinary examination may aid in discovering cases of long standing where a previous history is unknown.

8904 BIOCHEMICAL DIFFERENTIATION OF ENTEROBACTERIA IN THE CLINICAL BACTERIOLOGICAL LABORATORY. (Fr.) Renoux, G. (St. Eloi Clin., Montpellier, France) and E. Despaux. *Path. Biol. (Paris)* 15(7-8):432-435, 1967.

A simplified method for the biochemical differentiation of *Enterobacteriaceae* is described which can be applied in the normal clinical laboratory, and which the authors have been using for the past 3 yr. (in addition to the lysine-decarboxylase test). The method is based on urease detection, acidification of glucose and lactose, and β-galactosidase detection, with identification according to a dichotomy scheme devised by the authors. The culture media and reagents used include urea-indole, Kligler's lactose-glucose

H_2S medium, Kovacs' reagent, orthonitrophenyl-β-D-galactopyranoside, mobilized mannitol, Simmons', Clark and Lubs', Loeffler's, Kohn's, Christensen's and others. The following conclusions were drawn from the author's experience: Gram-negative bacteria which alkalize or fail to alter Kliger's medium are not Enterobacteria; Pseudomonas can be differentiated from Enterobacteria by the oxidase test; Aeromonas can be distinguished from β-galactosidase-positive Enterobacteria by the oxidase test; Aerobacter aerogenes differs from Aerobacter cloacae by its action on gelatin, glycerine, and inositol; β-galactosidase-negative Citrobacter can be distinguished from Salmonella by the lysine decarboxylase and KCN tests; Serratia differs from Enterobacteria inasmuch as they are gelatin-positive and fail to ferment arabinose; Providencia (Proteus) are correctly identified by the tryptophan-deaminase and urea-indole tests; Alkalescens and Dispar are usually citrate (Christensen)-positive; correct identification of Shigella and Salmonella is usually completed by serological tests.

8905 THE METHOD OF CONTRAST PERITONEOGRAPHY. (Rus.) Malkin, B. M. (Moscow Region. Res. Clin. Inst.). Vestn. Rentgen. Radiol. 42(1): 41-48, 1967.

A study was made on 22 rabbits and 8 dogs with 50% and 70% soln. of iodopyracet (Diodone) as the contrast preparation. In Series 1 (12 rabbits, 4 dogs), it was found that contrast peritoneography with iodopyracet (2-15 ml inj. intra-abdominally) enabled the detection of small amounts of fluids and their locations in the abdominal cavity. In Series 2 (8 rabbits), contrast peritoneography (iodopyracet was inj. under visual X-ray control into the area to be studied) facilitated the development of X-rays with a clear picture of individual organs of the abdominal cavity; e.g., liver, stomach, spleen, intestinal loops, bladder, etc. In Series 3 (10 rabbits, 2 dogs) it was found that admin. of water-soluble contrast preparations (in particular, 50%-70% iodopyracet) into the abdominal cavity produced no evident morphologic changes in the animal during an observation period of from 30 min.-8 mo. after admin. of the contrast medium. In Series 4 (4 dogs with Thiry-Vella intestinal fistulas), there was an inhibitory effect of iodopyracet on intestinal motility, i.e., after intra-abdominal admin. of iodopyracet there was inhibition of motor activity of the small intestine of up to 2 hr. duration; some of the animals were restless and in some there was a brief increase in respiratory frequency. The addition of 0.5% novocaine soln. to the contrast medium prevented the inhibition of motor activity of the small intestine, or the latter was brief (5-10 min.) with subsequent restoration of its normal amplitude of contraction; frequently, the contractions were stimulated. Thus, the method of contrast peritoneography could be effectively used for early recognition of closed injuries and acute inflammations of the abdominal cavity, particularly peritonitis.

8906 A COMPARISON OF TWO ANTIBIOTIC REGIM
IN THE TREATMENT OF GASTROENTERITIS
MALNOURISHED CHILDREN WITH A ONE-YEAR FOLLOW-U
OF THEIR SUBSEQUENT PROGRESS. (E.) Wittmann,
(U. Cape Town, South Africa), A. D. Moodie and
J. D. L. Hansen. S. Afr. Med. J. 41(16):414-4
1967.

A study was made on 101 children (62% males;
2 mo.-2 yr.) with clinically detectable dehydr
tion associated with diarrhea and vomiting. F
and electrolytes (M/6 sodium lactate, 5 ml/pou
the remainder as half-strength Darrow's soln.
2.5 dextrose; all over 24 hr.) were replaced b
scalp vein infusion. They received no milk du
the first 24 hr. and were then fed reconstitut
dried skimmed milk (2.5 ounces/pound) or were
breast fed. Drug therapy consisted of 1 of 2
regimens: 1) 1 i.m. inj. Benzathine penicilli
(300,000 U) + sulfadiazine suspension admin. p
for 5 days in a total dosage of 90-120 mg/pour
in 4 divided doses/day; 2) chloramphenicol pal
mitate p.o. for 5 days in a total dosage of
40 mg/pound/day in 4 divided doses/day; all fo
2 wk. Results of therapy were based on mother
reports of duration of diarrhea. Therapy was
considered successful if diarrhea stopped in t
first wk. and did not recur in the second. Pa
tients were classified as: less than 60% (10
60-75% (35), more than 75% (53) of expected wt
Failures to respond were 90%, 58%, and 30%, re
They were also classified into low, normal an
low plus normal wt. groups. Failures for the
groups were: 41%, 18%, 33% in Regimen 1; 69%
45%, 31% in Regimen 2. Results in favor of
Regimen 1 were statistically significant. Ni
died in the 2 wk. All 7 treated by Regimen 2
died, died within 1 wk., 5 with symptoms of g
malnourishment, while the 2 in Regimen 1 were
reasonably well nourished. Further follow-up
was made on 85 (9 deaths, 7 losses to follow-
Of 64 low and 37 normal wt., 51 and 29, resp.
continued through the study. Results in foll
were: mortality (9% low, 0% normal); kwashio
(18%, 7%); recurrent severe diarrhea (63%, 38
recurrent mild diarrhea (11%, 46%); no diarrh
(18%, 28%); wt. loss (59%, 14%), normal wt. a
1 yr. (29%, 86%), prolonged hospital treatmen
(13%, 7%). In the first wk. 90% of the death
occurred; rate for the whole yr. was 14%. On
3 of 14 who died were normal in wt. There wa
no difference in incidence of infection betwe
those who died and the others.

GASTROINTESTINAL DISEASES

GENERAL

47 DISABILITY FROM DISEASES OF THE DIGESTIVE
SYSTEM. (E.) (Ed.) Statistical Bull.
tropolitan Life Insurance Co. 48(April):10-12,
67.

special study of the Metropolitan Life Insurance
mpany employees covered by group insurance
owed that digestive diseases accounted for
% of the new cases lasting for more than a wk.
ring the period 1963-64; the percentage for
n was 17 and for women 10.4. The incidence of
l cases for men was 104.3/thousand and of all
ses for women 196/thousand; all diseases of
e digestive tract for men were 18.5/thousand
d for women 20.4/thousand. The incidence of
sability from digestive disorders rose rapidly
th advance in age, especially for the men.
tween the age groups 17-24 and 45-64 the
cidence more than triples for men and almost
ubles for women. In the oldest age group
cidence of disability due to digestive tract
almost the same for both sexes, about 28/thou-
nd. Some digestive disorders showed marked
fferentials in frequency by sex; hernias of
e abdominal cavity disabled males five times
re frequently than women, but diarrhea and
teritis occurred 3.5 times more often among
men; ulcers were somewhat more frequent among
n. Gastric and duodenal ulcers and hernias
the abdominal cavity accounted for more than
lf of all male disabilities due to digestive
sorders; disability from ulcers increased from
l/thousand at ages 17-24 to 7.3/thousand at
es 45-64; the rise due to abdominal hernias
s even steeper, 1.1 to 8.6/thousand. Disorders
the gallbladder, diverticulitis, and disorders
the anal and rectal region became important
uses of disability in the age group 45-64.
male employees were incapacitated more often
diarrhea and enteritis than by any other
sorders of the digestive system. At ages 45-64
cers, gallbladder diseases, diverticulitis and
seases of the buccal cavity and esophagus
came important causes of disability among women.
pendicitis was an important cause of disability
both sexes below the age of 25 yr. Claim
cords relating to disabilities from digestive
sorders point to associated emotional stress
re often than with most other causes of dis-
ility.

48 PROGRESSIVE CALCIFICATION OF THE DIGES-
TIVE TRACT ARTERIES, CLINICAL AND
TERIOGRAPHIC DATA IN 6 CASES. (Fr.) Debray,
(Bichat Hosp., Paris), J. Leymarios, J. P.
rdouin, M. Cerf, J. A. Paolaggi and C. Hernandez.
esse Med. 75(14):691-696, 1967.

e first patient had excruciating epigastric
in; no pulse could be detected in the legs;
epigastric murmur was present. Radiology of
e digestive tract was negative. Translumbar
rtography showed the following arterial
omalies: (1) Upper abdominal aorta of irregular caliber. (2) Aorta seemed to end at L-3-L-4. (3) No visible inferior mesenteric artery. (4) Superior mesenteric artery, a stump of 3mm. (4) Celiac trunk large (7 mm diameter). (5) Large left lumbar artery from aorta extending to limit of exposure. (6) Whole digestive tract supplied by hypertrophic celiac artery. (7) Lower left abdominal region supplied by a lumbar artery. Patient was operated upon despite poor arterial condition. Total obliteration of the superior and inferior mesenteric arterial lumens had occurred at their origin. The superior mesenteric reduced to a fibrous cord was patched with vein; no pulse was recovered in these arteries. The patient died; autopsy showed massive infarct of the intestine. The second subject admitted for gastric ulcer had an abdominal murmur, latent peripheral arthritis and a complete ostial obliteration of the celiac trunk and the superior mesenteric. The digestive tract and its associated glands were entirely supplied by the inferior mesenteric artery aided by a complex collateral circulation, most conspicuously a greatly enlarged arcade of Riolan. The third case suffered from pain suggesting ischemia of the digestive tract. Aortography showed stenosis of the celiac trunk without any interference with the superior mesenteric. Upon operation a felt-like impeding growth surrounding the celiac trunk was removed; in the weeks following operation the pain was much reduced. The fourth patient suffered from localized abdominal pain. The hepatic artery proved to be stenosed and surrounded by a felt-like growth. After corrective surgery, the patient had no pain and follow-up arteriography revealed a normal hepatic circulation. The fifth and sixth cases showed obliteration of the ostium of the celiac trunk with enlargement of the superior mesenteric as the chief compensating artery. Such arterial obstruction and obliteration incurs the development of extensive collateral circulation appearing as dilated and convoluted, pathologically-anastomosing arteries. Such arteries are of major practical significance: cutting or ligating them accidently during surgery can produce acute ischemia and gangrene of the intestine.

8949 ALLERGIC GASTROENTEROPATHY. A CAUSE OF EXCESSIVE GASTROINTESTINAL PROTEIN LOSS. (E.) Waldmann, T. A. (NIH, Bethesda, Md.) R. D. Wochner, L. Laster and R. S. Gordon, Jr. New Eng. J. Med. 276(14):761-769, 1967.

Six patients (4 males, 2 females; 2.4 mo.-14 yr. old) with a syndrome of edema, anemia, hypoalbuminemia, hypogammaglobulinemia, eosinophilia and growth retardation are described. Each patient had a normal or increased rate of albumin synthesis; each had a markedly shortened albumin survival half-time of 2.8-3.9 days, as compared to 17 ± 3 days in 14 controls. Fecal excretion of ^{131}I-labeled polyvinylpyrrolidone and ^{51}Cr-labeled albumin after i.v. admin. of these macromolecules was increased markedly; this indicated that gastrointestinal protein loss was responsible for the short survival of albumin, and the consequent hypoproteinemia. Such currently known causes of protein-losing gastroenteropathy as intestinal lymphangiectasia, celiac disease and agammaglobulinemia were excluded as underlying factors in this syndrome. Several factors suggested that gastrointestinal allergy may have been the cause of the protein-losing gastroenteropathy. There was a significant amelioration of clinical symptoms and disorders of protein metabolism in 3 patients studied on an elimination diet (specifically on a milk-free diet). When milk was reintroduced into the diet, diarrhea and vomiting, increased eosinophilia and an increase in the number of Charcot-Leyden crystals in stools developed, and the protein-losing gastroenteropathy worsened. Other features suggestive of an underlying allergic process included extreme eosinophilia in 4, presence of Charcot-Leyden crystals in the stools of 4, presence of precipitating antibodies to milk in the serum of 3, a family history of allergic disorders in 4 of the 5 infants in the series, and clinical manifestations of allergy such as persistent rhinitis, eczema and asthma in 4. In addition, there was a favorable response to admin. of corticosteroids (prednisone). The term "allergic gastroenteropathy" is suggested for this syndrome.

8950 HEMODYNAMIC AND METABOLIC CHANGES ASSOCIATED WITH BACTERIAL PERITONITIS. (E.) Rosoff, L. (U. Southern California Sch. Med., Los Angeles), M. Weil, E. C. Bradley and C. J. Berne. Amer. J. Surg. 114(2):180-189, 1967.

Hemodynamic and metabolic studies were performed on 10 patients critically ill with diffuse bacterial peritonitis, without concurrent diseases or lesions which could be productive of shock, such as hemorrhage, pancreatitis, myocardial infarction or major trauma; in 9 patients the bacterial peritonitis was enterogenous and in 1 hemorrhagic necrosis and i.p. rupture of a large degenerating myoma of the uterus was the initiating cause. Eight of the 10 patients died. Cardiac output and velocity of blood flow were normal. Total peripheral arterial resistance was markedly reduced in patients in whom systolic blood pressure was reduced to 75 mm Hg or less, despite normal cardiac output. Blood lactate levels were greatly elevated in these patients, indicating a critical reduction in blood flow necessary to sustain normal metabolism of vital tissues. There was an elevation of SGOT levels, which was evidence of cellular injury resulting from inadequate tissue perfusion or due to the primary lesion. These results indicate that an abnormal variation in distribution of blood flow is an outstanding circulatory alteration in patients with diffuse bacterial peritonitis; this hemodynamic effect may be explained by arteriovenous shunting in the systemic vascular bed. The site of such shunting is unidentified, but presumably occurs in the area of peritoneal inflammation. Decreases in alveolar O_2 exchange also indicate the coexistence of arteriovenous shunting in the pulmonary circula-
tion. Ventilatory failure and profound alterat
in pulmonary function appear to be significant
factors in the lethality of diffuse bacterial
peritonitis.

8951 VARIABILITY OF GASTRIC SECRETION IN
PATIENTS WITH AND WITHOUT THE ZOLLIN
ELLISON SYNDROME. (E.) Winship, D. H. (Marqu
U. Sch. Med., Milwaukee, Wis.) and E. H. Ellis
Lancet 1(7500):1128-1130, 1967.

Repeated histamine stimulation tests and measu
ment of 12-hr. (overnight) basal acid output
were made in 8 patients (a 14-yr.-old boy and
3 men, 4 women, aged 26-68) with severe, recur
peptic ulcers, prior to surgery. Operation
confirmed Zollinger-Ellison Syndrome in 4 of 8
although all were suspected of having this
syndrome. Preoperative testing (with at least
2 days between any 2 tests) in 7 patients show
striking variations in secretory patterns,
especially in basal acid secretion. Among the
patients with the surgically confirmed syndrom
preoperative studies, as above, were negative
in 1 of 4, and emergency surgery required in
another precluded repetition of histamine stim
tion. All of the 4 without surgically confirm
syndrome showed striking degrees of gastric
hypersecretion, with at least 1 element of the
secretory pattern suggesting the diagnosis in
each. The variations seen, especially in term
of basal acid secretion, were similar to the 4
without surgical confirmation of the syndrome.
Of this unconfirmed group of 4, 1 showed a lar
gastric ulcer, and the other showed active
duodenal ulcer craters.

8952 ACUTE SURGICAL ABDOMEN IN PATIENTS
WITH BURNS. (Bul.) Ranev, D., A.
Atanasov and N. Angelov. Khirurgiia (Sofia)
19(5):451-455, 1966.

Of 1400 patients treated for burns, 67 had var
forms of acute surgical abdomen (gastrointesti
tract hemorrhage, 15; gastric and duodenal ulc
perforation, 2; acute gastric dilatation, 37;
acute pancreatitis, 1; acute cholecystitis, 1;
other diseases, 11). Acute surgical abdomen i
a serious complication which develops from a
severe general condition and creates difficult
in diagnosis and treatment. Hemorrhages of th
gastrointestinal tract are accompanied by gast
and intestinal necrosis and acute gastric dila
tion. Diagnosis, clinical course and treatmen
these different forms of acute surgical abdome
are discussed, and case histories of 6 patient
(all male; 3-36 yr. old) with burns are given
detail. Hemorrhages of the gastrointestinal t
were separated into 2 groups. Group 1, dystro
changes in the stomach and intestine occurring
during the period of shock and the first days
toxic infection, were treated by conservative
therapy followed by surgery; and Group 2, gene
capillary toxicosis, found during the period o
toxic infection, were treated with cortisones,
antihistamines, etc. Acute gastric dilatation
developed at the termination of shock and duri

xic infection; these are treated by gastric nsing, blood transfusions, electrolyte soln., tamins, cardiac drugs, etc.

53 CHARACTERISTICS OF ACIDOSIS IN INFECTIOUS DIARRHEA OF THE NEWBORN. (Ger.) Kerpel- onius, E. (U. Budapest, Hungary) and G. Gyódi. Kinderheilk. 99(4):338-346, 1967.

e role of acidosis as well as of a number of her factors in the high mortality of premature fants was studied in 42 such infants from 3-42 ys old with birth wt. of 1100-2100 g. Infection Escherichia coli was a contributing entity. ood was obtained by arterial puncture. pH, O_2, excess base, and standard bicarbonate were termined. The pH of the blood of 13 was less an 7, of 9 between 7.01 and 7.15, and of 15 tween 7.16-7.30. Of the 13, 7 died; of the 9, died; and of the 15, 2 died. This clearly owed the relationship between early mortality d acidosis. The premature acidotic upon autopsy d anatomical changes, brain hemorrhage, intestinal rforation and bronchopneumonia; 2 infants lived r 12 days and 20 days despite severe acidosis die from infection. E. coli was found in all ternal organs investigated in 1 and the other ed decompensated in a hypoglycemic episode. The idosis at times developed with extreme rapidity; usually large amounts of bicarbonate were quired to correct the acidosis of metabolic igin and only in part compensated by respiration. e acidosis was much more persistent in the emature than in older infants. Thus the rtality among the premature seemed to be sociated with acidosis arising from faulty tabolism, leading to, or linked with, infection the infants with consequent septicemia and equent marasmus, sometimes complicated by ontaneous hypoglycemia.

54 ABSORPTION OF CHOLERA TOXIN INTO BLOOD FROM A SEPARATED JEJUNAL SEGMENT. (E.) ughan Williams, E. M. (Haffkine Inst., Bombay) d A. N. Dohadwalla. Nature (London) 215(5100): 2-553, 1967.

fant rabbits were equipped with a separated gment of jejunum, with 1 end blind and the other ening to the exterior as a fistula (Thiry loop), d the continuity of the remainder of the gastro- testinal tract was restored by anastomosis. In animals, rabbit passaged Vibrio cholerae Inaba 9B organisms were introduced into the separated gments at operation, or 24 or 48 hr. later. control animals, 0.2 ml of sterile medium was troduced into the segment opening onto the skin ther at operation, or 24 or 48 hr. later. urteen of the infected animals were dead within hr. of infection; 10 of 14 had diarrhea before ath and in 7 it was severe. At postmortem, a stended cecum and colon, containing clear rice- ter fluid and flakes of intestinal contents re found in all but 1 of the animals. Of 7 fected animals which lived more than 48 hr., had diarrhea. Fluid taken from separated segments of 8 animals grew cultures of V. cholerae. It is concluded that a toxin of principal importance was absorbed into the blood of infant rabbits from V. cholerae in a separated segment of jejunum and produced characteristic signs of cholera in the animal.

8955 AN EXPERIMENTAL STUDY ON THE PATHOGENESIS AND PREVENTION OF PERITONEAL ADHESIONS. (Jap.) Ohtawa, Y. Igaku Kenkyu (Acta Med. [Fukuoka]) 36(5):548-564, 1966.

Three groups of dogs (10 kg) were laparatomized and peritoneal adhesions stimulated by mechanically abrading the surface of the ileum or by application of chemical agents to the ileum in a standardized procedure involving 10 linear cm of the intestine. Both methods produced adhesions of the same degree of severity in the group of animals receiving no other treatment (control group). Histamine levels (determined by chromatography) in this group rose gradually to a max. within 6 hr. which av. 49 μg/g of ileum and yielded in other animals in this group an adhesion index of 0.99. In the second group each animal received a series of 5 i.v. inj. of sinomenine, each 5 mg/kg body wt. before the abrading or chemical treatment. Not only was the level of histamine much reduced (av. max., 16.9 μg/g of ileum) but the adhesion index was only 0.10. The animals in the third group were subdivided and treated with 2 different antihistamines, methdilazine HCl (Tacaryl) and diphenylhydramine (Restamin). Methdilazin was admin. only after the operation (1 mg/kg x 4); the adhesion index was 0.63. Diphenylhydramine was admin. to 2 series of animals: 1 series received 3 mg/kg i.m. for 4 times after the operation; the adhesion index was 0.42; the other series received 3 mg/kg i.m. for 3 times before the operation and 3 mg/kg i.m. for 4 times after the operation; the adhesion index for this series was 0.18. The histamine levels were about proportional to the adhesion indices. A significant suppression of the inflammatory reaction was seen predominently in the second group, pretreated with sinomenine, upon histological study.

8956 CARDIAC FAILURE IN KWASHIOKOR. (E.) Wharton, B. A. (Med. Res. Council Unit, Kampala, Uganda), G. R. Howells and R. A. McCance. Lancet 2(7512):384-387, 1967.

CLINICAL AND HISTOPATHOLOGICAL INVESTIGATIONS OF THE RESULTS OF LARYNGECTOMY FIED BY POLYESTER COATING OF THE OESOPHAGEAL . (E.) Radzimiński, A. (Med. Acad., Lodz, nd) and S. Szendzikowski. Acta Otolaryng. ckholm) 63(4):377-383, 1967.

rol examinations, on 15 surviving patients of otally laryngectomized for cancer, were made yr. after the operation where knitted Dacron were implanted to reinforce the esophageal . The 15 patients did not report any serious laints, were able to swallow liquids and d food normally, the scar was smooth in the operative area, and no apparent thickening he skin or within the underlying tissues rred. No fistulas were encountered. Allotic reinforcement of the esophagus was pered in 8 other patients previously subjected -ray cancer therapy; in 5 of these patients surgical wound was totally healed within 10 of surgery; in 2 patients skin and muscle osis developed necessitating the excision of necrotic tissue. The polyester net became ded; in spite of this, the peripheral parts he implant became satisfactorily incorporated subsequent complete healing and normal scar ation. In the last patient extensive necrosis local suppuration caused total sequestration he implant and resulted in an esophageal ula. The use of Dacron nets seems to reduce operative complications after X-ray therapy, necessity of prolonged postoperative treat-, and further multistage plastic operations. ication of knitted polyester net after ngectomy provides conditions favorable to closing of tissue defects as well as complete ing of the surgical wound. Of the 5 patients lly laryngectomized who died within the first operative yr., 4 died of cancer and the fifth on the 16th postoperative day from bilateral renous pneumonia and circulatory failure. his last case necrotic tissue had not dised the implant; the peripheral parts of the were already incorporated and tightly bound he surrounding tissue; parts of the net were ed with poorly vascularized granulation ue with multifocal inflammatory infiltration ly of neutrophil granulocytes. One case g of recurring cancer showed dislocation of implant with formation of a fistula; the r portion of the net was incorporated.

5 LOSS AND REGENERATION OF THE ESOPHAGEAL MUCOSA IN PEMPHIGOID. (E.) Foroozan, VA Hosp., Milwaukee, Wisc.), T. Enta, D. H. hip and J. S. Trier. Gastroenterology 52(3): 558, 1967.

al esophageal biopsies (13 esophageal, 2 nal, 2 rectal) were studied from a 71-yr.-old with pemphigoid after he had sloughed a of the esophageal squamous epithelium. ial biopsies showed no evidence of esophageal epithelium by conventional histological technics, whereas jejunal and rectal biopsies were normal. Clinical symptoms were minimal, although significant abnormalities in esophageal motility were demonstrated. Histologically detectable epithelial regeneration began during the fourth week following loss of the epithelium, and regeneration appeared to progress at the same rate along the entire length of the esophagus. Esophageal motility reverted toward normal within 2 mo. after loss of epithelium. Some residual thinning of the squamous epithelium of the esophagus persisted even after 8 mo. No stricture formation was noted.

9016 FIBEROPTIC AND CONVENTIONAL ESOPHAGOSCOPY IN THE DIAGNOSIS OF ESOPHAGEAL VARICES. A COMPARISON OF TECHNIQUES AND OBSERVERS. (E.) Conn, H. O. (VA Hosp., West Haven, Conn.), H. Binder and M. Brodoff. Gastroenterology 52(5):810-818, 1967.

Both Ba contrast examination and esophagoscopy methods have proved unsatisfactory. Splenoportography presents difficulties and ammonia tolerance tests are indirect and inferential. The present investigation compared conventional with fiberoptic esophagoscopy in the same patients at the same time. Ba esophagograms and ammonia tolerance tests were used as relative, rather than absolute, evidence of the presence or absence of esophageal varices. In the 54 patients of the experimental population esophageal varices were reported by the conventional Eder-Hufford esophagoscope in 21 (39%) and by LoPresti fiberoptic examination in 19 (35%). There was agreement among the methods in 70% of the trials. Radiological interpretations supported conventional esophagoscopic diagnosis in 37 (69%) and fiberoptic interpretations in 35 (65%). Ammonia tolerance tests agreed with conventional esophagoscopy in 31 of 41 patients (76%) and fiberoptic esophagoscopy in 29 (70%). The latter procedure was accepted by patients as easier than conventional esophagoscopy. Diagnostic discrepancies resulting from the use of the 2 methods could be attributed to observer variation along with differences in procedural technic. It is concluded that fiberoptic esophagoscopy in experienced hands appears to provide safe and reasonably accurate diagnosis of esophageal varices, although the need for precise criteria is emphasized.

9017 ESOPHAGOPLASTY BY INTESTINAL TRANSPLANTATION TO THE NECK. AN EXPERIMENTAL AND CLINICAL STUDY. (Fr.) Noirclerc, M. (Salvator Hosp., Marseille, France), C. Malmejac, J. M. Paoli and J. Dor. Ann. Chir. 21(7-8): 394-399, 1967.

Esophagoplasty was tried in 2 series of dogs and later in 2 humans. In the first series of dogs, transplantation of a segment of the small intestine was made into the neck region with proper vascular connections; in the second series the intestinal segment was grafted in place of the esophagus. Resection of 30-40 cm of intestine was not difficult in a dog weighing more than 25 kg. In the upper region of the small intestine a resection caused difficulties due to destruction of extensive lymphatic vessels in the superior mesentery; a segment of ileum excised just above the ileocecal junction was ideal; this region is supplied by network of vessels. Continuity of the ileum was re-established by end-to-end anastomosis; meanwhile the excised segment was perfused by heparinized aerated blood, as the neck was prepared for the transplant or graft; the superficial lateral region of the jugular in the neighborhood of joining with the facial vein was used for the venous connection. Arterial connection was made with 1 of 3 arteries; the common carotid, the superior thyroid, or the external carotid. Excision of the esophagus preceded grafting in the second series of dogs. The apparatus of Nakayama was used for arterial anastomosis while the veins were sutured by hand. There were 19 dogs in the first series; the blood vessels were open in all cases at the onset; in 6 cases thromboses formed in a short time; in others, vascular connections developed *in situ*. The 4 animals in the second series survived with functional grafts. The 2 human subjects were operated upon in the same manner with the addition of vascular connections to the internal mammaries in the region of the second and third intercostal spaces due to the greater size of the grafts; in 1 case death occurred on the sixth postoperative day due to retroperitoneal hematoma in the mesosigmoid region; the graft was in excellent condition at autopsy. The second case was successful and functional.

9018 GASTRIC ULCER AT THE NECK OF THE HIATAL HERNIA. (Fr.) Ledoux-Lebard (Cochin Hosp., Paris), Y. M. Laurent, D. Lallemand and G. De Vannoise. *Progr. Med. (Paris)* 94(20): 801-808, 1966.

Specific symptoms have not been observed in this condition. A gastric ulcer alone, or an isolated hiatal hernia can give rise to the same type of symptoms: postural pain, belching, pyrosis, regurgitation, dysphagia. As in all gastric ulcers the symptoms tend to be periodic. Certain complications, common to the 2 disorders also occur in this condition; hypochromic anemia and hemorrhage. Epigastric cramp is very frequent, especially in conjunction with pyrosis, often periodic. Excessive vomiting may produce esophagitis with perforation sometimes occurring. The radiologic pictures are variable. The hernia, often in the shape of a fist, may be very large; very frequently the mucosa of the herniated pouch is abnormal with thick irregular folds. The ulcer, usually in the small curvature, sometimes reached 3 cm in diameter; in other cases it was very small. Reports of hiatal hernia in association with adjacent ulce are rare in the literature. This report is based upon 11 cases. The patients, (from 40-90 yr. old) were about 66% women, and 75% were anemic with depressed RBC. Surgical results were excellent with only 1 death in a 78-yr.-ol man, whose generally poor condition precluded operation and who therefore was treated medical Others treated medically were much improved, although the hernia was not reduced.

9019 OESOPHAGEAL HIATUS HERNIA: LONG-TERM RESULTS OF THE CONVENTIONAL THORACIC OPERATION. (E.) Pearson, J. B. (Queen Elizabe Hosp., Birmingham, England) and J. G. Gray. *Brit. J. Surg.* 54(6):530-533, 1967.

A total of 64 patients (45 women, 19 men) were reviewed on an av. 6.5 yr. after surgical repai of their hiatus hernias by the Allison procedur 45 were seen 5 or more yr. after operation. Symptoms were present for more than 4 yr. in over half at the time of operation. Predominan symptoms included pain and heartburn in 46, regurgitation in 34, vomiting in 25 and dysphagia in 20. Ten patients attributed the onset of their symptoms to pregnancy and 3 patients had a family history of hiatus hernia. Scoliosis, often stated to be associated with hiatus hernia, was present in only 1 patient while preoperative radiography revealed the presence of reflux in all patients. Of 56 with visible hernia, 5 had the paraesophageal variety, 3 of which were associated with slidi hernia, the most common type. The sliding hernia was large in 15 and incarcerated in 10. There were 2 patients with stricture and 1 with esophageal ulcer (peptic). Esophagoscopy of 14 patients before operation indicated 10 with esophagitis and 3 with a stricture not shown radiographically. No operative mortality occurred. The av. hospital stay after operatio was 15 days. One patient had a recurrence of hernia through the hiatus in the first 24 hr. and was cured with reoperation on the second da 4 patients developed deep-vein thrombosis in th legs and 1 had a small pulmonary embolism. The 31 patients assessed as cured were completely symptom-free at follow-up time; 22 improved patients had mild complaints only and considere the operation worthwhile. There were 11 patien unimproved, thus clinical successes numbered 53 of 64 (83%). This contrasted with only 40% considered as radiological successes. Of 31 wh were completely symptom-free, 11 had reflux on Ba swallow; in addition to reflux, 3 had small hiatus hernias and 1 a paraesophageal hernia. Of 22 cases who improved but were not cured, 15 reflux, (a higher proportion than in the cured group); besides reflux, 5 had small hiatus hernias and 1 a paraesophageal recurrence. Seven of 11 failures had reflux; all had hiatus hernias, and 1 had a stricture. Thus, radiological successes numbered only 22 of 55 (40%). It is suggested that closure of the hiatus behind the esophagus is responsible for the disparity between radiological and clinical

ults, and that suture of the right diaphrag-
ic crus in front of the esophagus, as recom-
ded by Collis, will produce better correlation
ween radiological and symptomatic improvement.

0 THE INCIDENCE OF HIATUS HERNIA AND THE
INCIDENCE OF ITS SYMPTOMS. (Ger.)
nberger, F. (Barmherzigen Bruder Hosp.,
zburg, Austria). Radiol. Austria 17(1):59-65,
7.

2409 examinations of the stomach, almost 20%
hiatal hernia. This high incidence may have
ulted in part from X-ray diagnosis of the
tus cardia in motion. Among the 2409 patients,
(19.7%) had hiatal hernia, 236 (9.9%) ulcers,
33 (1.4%) had neoplasms. Of those with
tal hernias, 65 were under 30 yr., 156 were
ween 30 and 50 yr., and 254 were over 50 yr.;
had definite symptoms; 180 had problematic
ptoms; 205 had no symptoms. Symptomatology
determined from medical history and X-ray
ords and included: dysphagia, retrosternal
n, reflux complaints, dependency of pain upon
ition, pressure in the upper abdomen; un-
asant sensation in the region of the stomach
heart, and pyrosis. Those with problematic
ptoms, i.e., the X-ray picture showed no
lux, the esophagoscope showed normal mucosa
the medical history was not definitely
racteristic, complained of pressure in the
er abdomen, unpleasant sensation in region of
mach and heart with pain eventually radiating
ard the left, and sometimes pyrosis. The
gest group (205 patients) had no pains
cifically attributable to hiatus hernia.

1 A DYNAMIC TEST OF SPHINCTER STRENGTH:
ITS APPLICATION TO THE LOWER ESOPHAGEAL
INCTER. (E.) Pope, C. E. II (U. Washington,
ttle). Gastroenterology 52(5):779-786, 1967.

surement of sphincter closure force was
ieved by utilizing intra-luminal infusion of
ter quantities of fluid. This infusion caused
elevation in recorded pressure (yield pressure)
en the catheter tip was within a sphincter.
yield pressure agreed exactly with the
sure force in a model sphincter and predicted
el sphincter strength more exactly than other
thods currently employed for sphincter measure-
t. The infusion system was used to study 40
jects whose degree of lower esophageal
incter competence was defined on either
nical grounds (heartburn) or by objective
asurement (Tuttle test). Subjects with
petent sphincters had significantly higher
eld pressures than did those without competent
hincters. The overlap of yield pressures was
ast when the presence or absence of competence
s defined by the Tuttle test. No significant
fference between competent and incompetent
hincters was found when resting lower esophageal
hincter pressures were measured. It is con-
uded that infusion of μliter quantities of
fluid into the lumen of a closed sphincter allowed more accurate prediction of sphincter closure force than did static measurement of intrasphincter pressure.

9022 OESOPHAGEAL SENSITIVITY TO MECHOLYL IN SYMPTOMATIC DIFFUSE SPASM. (E.)
Kramer, P. (Boston U. Sch. Med. Mass.), B. Fleshler, E. McNally and L. D. Harris. Gut 8(2):120-127, 1967.

A group of patients with symptomatic, diffuse esophageal spasm (8 men, 6 women, aged 38-73 yr.) received methacholine (2-3 mg, initial i.m. dose; increased by 2-3 mg per dose every 25 min. to max. doses of 6-10 mg or until a hypersensitive response was achieved). Characteristic, lumen-obliterating esophageal contractions were induced in 11 of 14 (in response to doses of 2-6 mg) with sufficient force to expel all the air from a balloon placed in the lower-third of the esophagus for balloon-kymography. In all 9 patients with asymptomatic, diffuse esophageal spasm (3 men, 6 women, aged 56-72 yr.), doses of 6-10 mg failed to induce more than very slight changes of motility, similar to those manifested by a group of normal controls over 50 yr. of age. Among the symptomatic patients, pretreatment tonus was elevated in 3 of 14; wave patterns were irregular in 8 of 14; manometric tracings confirmed diffuse spasm on swallowing in all 8 who were so tested, accompanied by opening of the sphincter in all 6 in whom this was also studied. Comparable tabulations among asymptomatic patients were 0 of 9, 7 of 9, 2 of 2 tested and 2 of 2 tested, resp. It is concluded that the varied patterns elicited by X-ray of patients with symptomatic, diffuse esophageal spasm may be only variant manifestations of the same hypersensitive response. It is also suggested that symptomatic, diffuse esophageal spasm and cardiospasm may be closely related in view of the similar response to parasympathomimetic agents shown by both groups of patients.

9023 STUDIES ON ESOPHAGEAL MOTILITY IN NORMAL SUBJECTS AND IN PATIENTS WITH HIATUS HERNIA AND SCLERODERMIC ESOPHAGEAL DISEASE. (Sp.) Dávila, M. (San Juan de Dios Hosp., Santiago, Chile), F. Rufín, E. Parrochia and R. Armas Cruz. Rev. Clin. Esp. 104(4): 316-322, 1967.

Esophageal motility was studied in 6 normal subjects (4 men and 2 women), 7 patients with scleroderma of the esophagus, and 5 patients with hiatus hernia. Two catheters and a microelectrode were inserted at the level of the middle portion of the esophagus and at the gastroesophageal junction; the catheters were connected to a Statham P23D6 Strain Gauge, to a Simultracer Recorder, and to a Beckman Zeromatic-type potentiometer. Motility was recorded under normal conditions, 10-15 min. after i.m. inj. of carbachol (0.25 mg), and 10-15 min.

following subsequent s.c. inj. of atropine (1 mg). In the region of the gastroesophageal sphincter, length, pressure (cm H_2O) at rest, relaxation, and during contraction were 4 cm., 7.52, 13.7, and 10.4, resp., in normal subjects; 2.5 cm, 3.9, -, and -, resp., in patients with scleroderma; 2.5 cm, 7.2, 14.5, and 13.1, resp., in patients with hiatus hernia. At the level of the middle portion of the esophagus, pressure at rest, pressure of contraction waves, and propulsion were -4.3 cm H_2O, 33.3 cm H_2O, and present, resp., in normal subjects; -2.4 cm H_2O, 6.9 cm H_2O, and absent, resp., in patients with scleroderma; -7.8 cm H_2O, 57.1 cm H_2O, and present, resp., in patients with hiatus hernia. Distinguishing characteristics in patients with scleroderma consisted of preservation of pharyngoesophageal sphincter and motility of the superior portion, altered function of the gastroesophageal sphincter and inferior portion, but positive response to carbachol (as opposed to patients with achalasia). The most frequent signs of hiatus hernia included sphincter ascension (2 patients), double respiratory inversion (2), sliding (2), sphincter elongation (1), double pressure peak (1), hypo-relaxation (1), and hypercontraction (1). The value of the technic in the diagnosis of esophageal diseases is stressed.

9024 ACHALASIA AND ESOPHAGEAL CARCINOMA. (E.) Just-Viera, J. O. (U. Michigan Hosp., Ann Arbor), J. D. Morris and C. Haight. Ann. Thorac. Surg. 3(6):526-538, 1967.

The incidence of carcinoma of the esophagus in patients with achalasia is probably higher than suspected since diagnosis is usually delayed due to the absence of early obstructive symptoms because of dilatation of the esophagus. In a series of 148 patients with achalasia, 5 have developed carcinoma. The 5 cases involved 5 men whose ages were 58 yr. in 2 cases, 43 yr. in 2, and 37 yr. in 1 case. This last case demonstrated that young patients with achalasia should be examined carefully since carcinoma of the esophagus occurs far earlier in patients with achalasia than normally. When the patient showed a change in symptoms, temporary improvement was obtained by transabdominal Heller myotomy, vagotomy and pyloroplasty, but since esophagoscopy was not performed, the neoplasm was not detected. Six wk. later when symptoms recurred, esophagoscopy led to detection and the neoplasm was removed but metastases were seen at operation. The patient died 6 mo. later. A similar pattern of symptom changes, as well as poor prognosis, occurred in the other patients where changes included clubbing, wt. loss, anemia, hematemesis and melena. In one case radiation therapy and radical surgery gave apparent control of the esophageal cancer as the patient is still living, 2.5 yr. following resection. Relief of stasis in patients with achalasia offers the best means of prevention of carcinoma, while surveillance consisting of esophagograms, cytological examination of esophageal secretion and esophagoscopy are essential.

9025 THE TREATMENT OF CARDIOSPASM. (Ger.) Reeh, K. (U. Clin. Frankfurt/Germany) and H. Blaha. Bruns Beitr. Klin. Chir. 214(3) 280-297, 1967.

A group of 61 patients with achalasia (29 male and 32 female without marked distribution of a or sex) were treated by nonoperative and then, if required, by surgical methods. Duration of achalasia from initial symptoms to examination prior to treatment was 5 yr. in 6 cases, 10 yr in 19, 15 yr. in 14, etc., to over 40 yr. for subjects. Mild and severe forms of achalasia occurred each with its own characteristics. T object of treatment was the coordinated passag of foodstuffs through the esophagus into the stomach while retaining the valvular function the cardia to prevent reflux; if this could be accomplished without surgery the risk of reflu esophagitis is greatly decreased or eliminated A tube for introducing food into the stomach i an emergency measure occasionally producing effective dilatation. The use of a bougie was sometimes required; for if a bougie will not p dilatation is not possible. The dilatation ca be pneumatic or hydrostatic or by instrument. The technic used was that of Starck. After a 24-hr. fast and premedication with atropine an pethidine (Dolgntin) and spraying the pharynx with tetracaine (Pantocain), the dilator was introduced into the esophagus; when in correct position the dilator was expanded and left expanded for a time. More than 1 session was sometimes required to attain max. stretching. Eleven patients showed improvement clinically and in X-ray examination; 31 others were great improved and underwent repeated treatment in only a few cases; relapse in only 2 instances required surgery. Eight different surgical technics are outlined while the one used in al except 2 cases was the extramucosal cardiomyotomy of Heller. Success is reported for 8 8 cases with the Heller operation, and the 2 performed by gastroesophagostomy were also successful. Medical treatment was required in only 9 patients. These cases were followed-up from 1-14 yr. with the surgical cases reportin no untoward symptoms.

9050 CLINICO-PATHOHISTOLOGICAL PARALLELS IN CHRONIC GASTRITIS IN PATIENTS OF DIFFERENT AGE.

(Rus.) Bialik, V. L., R. I. Koroleva, V. S. Novikov, V. Ia. Persidskii and I. A. Shlykov. Vrach. Delo 40(2):24-29, 1967.

A total of 1022 patients (978 men, 44 women) with chronic gastritis were studied. In 43 of Group 1 (8-17 yr. old), normal mucous membrane was found in 53.5%, superficial gastritis in 44.2%, deep gastritis in 2.3%, and atrophic gastritis in none; the values for 765 patients in Group 2 (19-25 yr. old) were 48.5%, 43.4%, 5.6% and 2.5%, resp.; for 154 patients in Group 3 (26-45 yr. old), values were 31.2%, 42.8%, 12.3% and 13.7%, and for 60 patients in Group 4 (46-70 yr. old) the values were 30.0%, 25.0%, 5.0% and 40.0%. Changes corresponding to superficial gastritis were observed in 8 of 32 apparently healthy persons. Increased acidity was found in 25.6% of Group 1, 48.4% in Group 2, 20.8% in Group 3 and 13.3% in Group 4; values for hypoacidity were 23.2%, 24.6%, 31.2% and 28.3%, resp.; for achlorhydria they were 4.7%, 7.8%, 24.0% 48.4%; and normal values were found in 46.5%, 19.2%, 24.0% and 10.0%, resp. An absence of morphological changes in the mucous membrane was found in 62.8% of those with hyperacidity, 51.1% of those with normal acidity, 31.2% of those with hypoacidity and 11.0% of those with achlorhydria. In hyperacidity deep gastritis was found in 2.2%, atrophic gastritis in 1.0%; values at normal acidity were 2.3% for deep gastritis and 1.4% for atrophic gastritis; in hypoacidity they were 9.2% and 5.0%, resp.; and in achlorhydria, 191.% and 39.0%, resp. Thus, increased histological changes of the mucosa paralleled the acid-forming ability of the stomach. Secretion of gastric juice was reduced in deep, and especially, in atrophic gastritis.

9051 X-RAY DIAGNOSIS OF EXCESSIVE MUCOUS MEMBRANE OF THE STOMACH.

(Rus.) Kagan, E. M. (Ministry Health, Moscow). Vestn. Rentgen. Radiol. 42(1):3-13, 1967.

In a study of 123 cases, excessive mucous membrane was located in all portions of the stomach, and was found infrequently in children and more often in subjects over 35-40 yr. old. At the time of examination or earlier, most of the patients had diseases of the digestive tract. Excessive mucous membrane was located in the cardia and gastric curvature in 22 subjects, in the gastric body in 87, close to the lesser curvature in 1, and in the antrum in 14. In the excessive mucous membrane, a variable picture and an absence of navicular traction of the serous membrane corresponding to an observed filling defect was noted; in exophytic material which had developed into an ulcerative or nonulcerative tumor, a variable picture was lacking and navicular traction of the serous membrane was present. In the excessive mucous membrane, the secretory and evacuatory gastric function were only slightly disturbed, if at all; normalization of mucous relief was absent after treatment and clinical
symptoms were absent or slightly pronounced.
gastritis, both gastric functions were disturb
mucous relief was normalized after treatment,
clinical symptoms were present. Differential
nosis of excessive mucous membrane is based on
same principles (therapeutic effects, pharmaco
cal tests); changes related to excessive mucou
membrane are based on a disturbance of hydrody
balance and edema on the basis of anemia, urem
allergy, and various endocrine disturbances.
importance in the differential diagnosis betwe
excessive mucosa and reticulosis are the clini
picture, laboratory data, the presence of enla
peripheral lymph nodes and data of their biops
and the results of radiation therapy. In reti
sis, altered mucosa could be normalized by rad
tion therapy, while excessive mucosa remained
ble under such therapy. Changes analogous to
varicose veins of the gastric cardia are usual
found in the esophagus, in contrast to excessi
mucosa. Basic radiological symptoms include:
ervation of peristalsis in the body and antrum
the stomach; pliability of the upper walls; ab
sence of a palpable tumor in the region of the
clearly visible filling defect; presence of an
additional shadow corresponding to the visible
filling defect; variability of the radiologica
picture in the process of examination and recu
rence of its basic properties even during a pr
longed observation; and a normal relief of the
mucous membrane along the lesser curvature. D
ing radiologic observation of 29 patients for
5 to more than 8 yr., no changes were found wh
compared to the initial picture. Three case histories are presented in detail.

9052 ELECTROGASTROPHY IN GASTRITIS, GASTR
DUODENAL ULCER AND GASTRIC CANCER.

(Rus.) Makos, R. P. (Ivano-Frankovsk Med. Ins
USSR). Ter. Arkh. 39(1):32-37, 1967.

Electric potentials (from the surface of the
body and mucosa of the stomach), motility, ton
and gastric secretion were studied in 19 patie
with gastric cancer; 37 with gastric ulcer and
with chronic gastritis (mostly males, 30-60-yr
old; 35 had hyperacidic gastritis, 23 hypoacid
and 28 anacidic) of 3-16-yr. duration and in 1
healthy normals (the controls; 22-45-yr. old).
Electrogastrograms revealed a complex of diffe
waves; rapid waves reflected rhythm and depth
of gastric contractions, slow, brief waves reflected fluctuations of gastric tonus, slow
waves reflected secretory activity, and large
drops of the recorded level reflected changes
in acidity. In stomach diseases, gastric elec
trical potentials changed in parallel with
motility, secretion and tonus; the character o
these changes reflected, to a large degree and
were dependent upon, the character of the path
logical process. In peptic ulcer and chronic
hyperacidic gastritis, there occurred hyperkinetic dyskinesia of fluctuations of electric
potentials, tonus and gastric contraction. In
gastric cancer, hypoacidic, and (especially)

idic gastritis, these fluctuations were hypo-tic compared to normal findings. The character, ee and duration of some medical compounds opine, antihypertensive agents, papaverine, amine, HCl) on motility, tonus and gastric etion were also reflected on the electro-rogram.

3 ARGENTAFFIN CELLS IN EXPERIMENTAL GASTRITIS. (Ger.) Rodriquez-Olleros, A. Puerto Rico, San Juan) and R. Barroso-Mogel. astroent. 5(2):75-78, 1967.

phic gastritis was produced in rabbits by itization to human gastric juice dialyzed at and then vacuum dried; a dose of 12 mg in ne was inj. twice/wk. for 12 wk. Papillomatous ritis was evoked in rabbits by instillation .5 ml of 0.5% croton oil in an equal vol. of hol-ether twice/wk. for 6-9 wk. Ulcerative ritis was caused in dogs by the twice/wk. n. of 2 g cincophen; the animals were killed days after the last dose. The stomach of y animal was fixed in formalin; thick sections stained with hematoxylin-eosin, and the ntaffin cells according to the method of oso-Mogel. The number of argentaffin cells he gastric mucosa in animals with experimental phic gastritis was definitely reduced. The er of these cells, however, was noticeably eased in animals with papillomatous gastritis ced by croton oil. In the edematous necrotiz-phase of erosive gastritis caused by cincophen, ntaffin cells were almost completely lacking, in this phase the covering epithelium showed plasia of goblet cells. Inasmuch as argentaf-cells are the source of serotonin, a change he relative number of these cells will affect functions controlled or affected by serotonin.

4 CLINICAL ASPECTS OF EXAMINATION OF THE GASTRIC MUCOSA BY BIOPSY. (Ger.) ger, H. (Kaiserin Elisabeth Hosp., Vienna). . Z. Inn. Med. 48(2):70-71, 1967.

tudy was made correlating 1) the histologic tures of the gastric mucosa of 360 patients, ailing 993 biopsies; 2) the degree of gastric dity; and 3) the age of the patients. As is wn, the greatest percentage of cases with eracidity had a normal gastric mucosa. In ients passing through the stages from super-ial to atrophic gastritis, hyper- and normal dity had disappeared, the degree of hypoacidity reached 80%, and increased to 86% in gastritis changing or already altered mucosal structure. case of complete achlorhydria was found in junction with a normal mucosa, although 13% normal gastric mucosa had mild hypoacidity 18% more pronounced hypoacidity. Cases of y pronounced hypoacidity were found in the up with an av. age of 28 with a histologically mal mucosa. Older patients with pronounced oacidity did not present a normal mucosa; these patients gastritis had progressed to the atrophic state in which the greatest incidence of hypoacidity and achylia were demonstrable; 8% of the older patients had hyperacidity, 18% had normal acidity, 35% mild hypoacidity, 26% pronounced hypoacidity and 13% achylia. Half of those having a normal gastric mucosa in the 50-70-yr. age bracket had hyperacidity. Those who retained a normal mucosa tended to hyperacidity whereas those with developing atrophic gastritis tended to become achylic.

9055 THE QUESTION OF THE CIRCUMSCRIBED AREA TYPE OF GASTRITIS. (Ger.) Frank, A. (Rudolfstiftung Hosp., Vienna). Wien. Z. Inn. Med. 48(2):57-65, 1967.

Biopsies were not sufficient for the certain diagnosis of "bedded circumscript gastritis." X-ray examination was of great value to differentiate this form of gastritis from neoplasms, as illustrated with 5 cases. The region affected in all 5 cases was the greater curvature; 1 case had no gastric acidity and in another acidity was deficient; all suffered stomach pain, or pain on palpation in the gastric region, X-ray examination revealed a circumscribed area, up to 9-cm in diameter, raised up to 15 mm, with numerous folds or plicae. Two of the 5 showed erosion of the mucosal surface. Conservative treatment was given in 3 cases, 2 were resected. The observation period of 1 of the operated cases extended over 8 yr. with no recurrence. The differentiation of this form of gastritis from cancer by X-ray is dependent upon 3 factors seen in gastritis: 1) Peristaltic movement is often well preserved, or at least pharmacologically provable. 2) The highly thickened plicae resemble gyri of the brain. 3) Repeated examinations show structural changes in the plicae. The erosion at the top of the gyri in 2 cases demonstrated the inflammatory genesis of these alterations. Lymphocyte infiltration was seen in the muscularis mucosae and in 1 instance, to a very minor degree, in the muscularis propriae. The mucosa itself in the affected areas was infiltrated with lymphocytes and plasma cells. "Circumscript bedded gastritis" may be a special form of erosive gastritis.

9056 OBSERVATIONS ON THE COURSE OF "GIANT FOLD" GASTRITIS. (Ger.) Ellegast, H. (U. Clin. Vienna) and N. Stefenelli. Wien. Z. Inn. Med. 48(2):51-57, 1967.

"Giant-fold" gastritis was observed in 23 cases for an av. of 3 yr.; the oldest case was of 14 yr. duration; in many of these the clinical and radiologic diagnosis had been confirmed by biopsy. A few patients have undergone gastroscopic examination. Cases with similar aspects have been mistaken for known malignant changes in the wall of the stomach, malignant changes in the mucosa, the result of systemic disease, allergic manifestations, and others; finally, it is recognized as a giant-fold formation which has no particular or peculiar clinical symptoms. This giant-fold formation in some ways resembles the Ménétrier Syndrome; however, in no case is it marked by a gastrointestinal loss of protein; there is never any adenomatosis of the mucosa. The patients are mostly between the ages of 40 and 60, and are about equally male and female, who experience a pressing pain in the stomach. A feeling of illness, vomiting, fatigue, loss of appetite and large wt. loss follow; at times, there is slight bleeding from the stomach; the stomach region becomes tender. Gastric secretion is increased. The radiologic picture shows the large, swollen, curving, continuing folds which do not disappear or become obliterated; these folds resemble gyri, sharply defined and circumscribed, they may be found in the fundus in the greater curvature of the body, the angelus as well as in the antrum. Peristalsis may be depressed but it is never destroyed as in some neoplasms. Histology of longer-standing cases shows infiltration of round cells, bleeding in the stroma. Hypertrophic changes of the mucosa have never been found. The course of the disease becomes uncommonly chronic in most cases, reaches a static condition and persists. Upon histologic observation over a period of yr. there seems to be a tendency toward atrophy of the mucosa. An improvement has been noted in only a very few cases.

9057 AGE DEPENDENCY IN GASTRITIS DEMONSTRABLE BY BIOPSY. (Ger.) Seifert, E. (Hanusch Hosp., Vienna) and H. Knoll. Wien. Z. Inn. Med. 48(4):145-151, 1967.

Biopsies were taken from the fundus of the stomach in 1000 cases with complaints of the upper abdomen. The determination of mucosal changes was according to the system of Henning and Heinkel: 1) normal; 2) light-to-moderate superficial gastritis; 3) moderately-severe to severe superficial gastritis; 4) superficial gastritis with beginning atrophy, 5) and atrophic gastritis or structural alterations resulting from gastritis. Patients between the ages of 14 and 70 yr. were investigated; younger patients did not appear in the division and older patients were too few to be included. Of the 1000 patients, 225 were in Group 1, i.e., normal; 322 in Group 2, 293 in Group 3, 95 in Group 4 and 65 in Group 5. In the age group 14-20 yr. there were 50 cases: 46% (1), 28.0% (2), 22.0% (3), 4% (4), and 0% (5); in the age group 21-30 yr., 143 patients, 49.6% (1), 28.0% (2), 21.0% (3), 7.4% (4), 0% (5); in the age group 31-40 yr., 178 patients, 33.7% (1), 34.2% (2), 27.0% (3), 3.4% (4) and 1.7% (5); in the 41-50-yr. group, 193 patients 13.1% (1), 43.0% (2), 29.0% (3), 17.8% (4) and 3.7% (5); in the 51-60-yr. group, 265 patients, 12.1% (1), 32.1% (2), 32.4% (3), 14.3% (4), 9.1% (5) and in the 61-70-yr. group, 171 patients, 8.2% (1), 22.8% (2), 36.3% (3), 14% (4) and 18.7% (5). The obvious shift is toward the right from the normal toward the atrophic in the advancing age groups. This is not, however, a true aging process but the result of inflammatory activity in a specially-select pathologically-inclined group of patients. Th authors believe that the patients with gastric atrophy show an inclination toward the develop of cancer.

9058 CHRONIC GASTRITIS IN THE REGIONS OF ANTRUM AND BODY. (Ger.) Friedrich, (Humboldt U., Berlin), G. Lisewski and H. Davi Deutsch. Z. Verdau. Stoffwechselkr. 26(5-6): 213-218, 1967.

Biopsies were taken in the antrum and body in the forward wall near the greater curvature fr 90 patients of both sexes. The tissues were prepared for histology by the usual methods. Henning's system for the classification of the gastric mucosa was followed: 0, normal mucosa I, minor superficial gastritis; II, definite, chronic superficial gastritis; III, chronic superficial gastritis with partial atrophy, IV chronic atrophic gastritis. The gastric chang were more marked in the body of the stomach of 12 patients and in the antrum of 33. In 45 ca full agreement between the antral and body fin ings occurred. Where differences occurred betw the histologic pictures of antrum and body the were usually only minor. In only 7 cases was the difference strong. The antral biopsy in most cases presents a true reflection of the bo biopsy.

9059 HISTOLOGICAL EFFECT OF CERTAIN PICKL ON THE HUMAN GASTRIC MUCOSA: A PRELIMINARY REPORT. (E.) MacDonald, W. C. (Cytological Diagnostic Lab., Vancouver, Britis Columbia), F. H. Anderson and S. Hashimoto. Canad. Med. Ass. J. 96(23):1521-1525, 1967.

By means of repeated peroral suction biopsies the histological effects of human gastric muco of the Japanese foods, sake lees (white cucumbe in rice wine mash), fukujinzuke (radish, eggpla beans, bamboo shoots and beefsteak leaves in soy sauce) and takuan (salted white radish) as well as gherkin pickles, raw carrots and raw cucumbers were obtained from 3 healthy males wh usually adhered to a Western diet. The ingesti of 30 ounces of fukujinzuke or of vinegar gherk over a 3-day period caused marked changes in th surface epithelium and gastric pits in all 3 subjects. The abnormalities consisted of loss of cellular mucus, nuclear enlargement, promine nuclear chromatin and an increased number of mitotic figures. After 20 ounces of fukujinzuk and 10 ounces of sake lees these abnormalities the surface epithelium and gastric pits were seen as well as a marked increase in mitotic count. Some changes were apparent after the ingestion of just 1 Japanese meal. These changes indicate a more rapid turnover of the cells of the pits and surface epithelium in response to irritation. Despite the epithelial cell change no increase was seen in the number of inflammat cells. All control biopsies were normal, as we

opsies after the ingestion of 30 ounces of
w carrots or cucumbers over a 3-day period.

60 SODIUM AND POTASSIUM CONTENT IN MIXED SALIVA OF PATIENTS WITH CHRONIC GASTRITIS
) GASTRODUODENAL ULCER. (Rus.) Vainshtein,
G. (Kazan Lenin Postgrad. Med. Inst., USSR).
r. Arkh. 38(11):37-39, 1966.

liva was obtained from 195 patients (20-65 yr.
d) during fractional study of gastric secretion
aliva secretion was stimulated using gastric
und as a mechanical irritant). The conc. of
and K (in mEq/liter) and the Na/K coefficient
44 patients (21 males, 23 females) with chronic
stritis and reduced acidity was 11.46, 20.52
d 0.57, resp.; in 40 patients (13 males, 27
males) with chronic gastritis and normal acidity,
ese values were 10.45, 20.1 and 0.57, resp.;
22 patients (15 males, 7 females) with chronic
stritis and increased acidity, they were 17.54,
.82 and 0.90, resp.; in 75 (65 males, 10 females)
th duodenal ulcers, values were 18.74, 20.84
d 0.93, resp.; and in 14 patients (12 males,
females) with gastric ulcers, the values were
.43, 20.50 and 1.31, resp. Thus, K conc. did
t fluctuate significantly, while Na conc. in
peracidic gastritis and peptic ulcers was sig-
ficantly higher than Na in the normoacidic
d hypoacidic states of gastritis. Analogous
rrelations were found between these groups in
lation to the Na/K coefficient. The possible
gnificance of these findings are discussed.

61 STUDY OF SO-CALLED GASTRIC ABSORPTION IN CLINICAL CONDITIONS. (Rus.)
immerman, Ia. S. (Perm. Med. Inst., USSR).
vet. Med. 29(12):18-21, 1966.

e permeability of gastric glandular cells was
udied in 174 patients who had various digestive
act diseases: Group 1, 21 patients with gastric
cer; Group 2, 113 patients with duodenal ulcer;
oup 3, 23 patients with chronic gastritis; and
oup 4, 17 patients with chronic cholecysto-
olangitis. Permeability was determined by the
thor's modification of the Pentzoldt-Faber
dine-potassium test, which proved to be a valu-
le indicator of the functional condition of
e gastric mucous membrane. The procedure was
follows: removal of the gastric content on a
sting stomach was followed by admin. of KI
ml of a 3% soln.) and minute determination of
e salivary appearance of iodine (using a 1%
ln. of starch and conc. HNO_3); this was followed
repeated removal of the gastric content and
min. of a test breakfast (7% cabbage decoction,
5% alcohol, etc.). Further examination was
nducted using the method of Lepor. Disturbance
permeability was highest in groups 1 and 3,
ile in the other 2 groups it was less signif-
ant. Permeability (in min.) in all of the
tients before treatment ranged from 11.1 to
.4, and after treatment from 8.3 to 12.215.
ter therapy the permeability (on an empty
stomach and during active secretion) increased in 66 of 102, remained unchanged in 27 of 102 and was somewhat decreased in 9 of the 102 patients; the latter group exhibited atrophy of the mucous membrane and gastric achylia. After application of paraffin in 42 patients (Groups 1-3), intragastric temperature increased by 0.5°; permeability decreased in 24 of 42, remained the same in 12 of 42 and was slightly increased in 6 of the 42 subjects. Titratable acidity of the gastric juice decreased and the digestive strength remained unchanged in 28 of 42. In 86 patients (Groups 1-3), a comparison was made between the therapeutic clinical effect and dynamics of basic gastric functions before and after treatment; this revealed a trend toward normalization of several gastric functions, such as the secretion of uropepsinogen (from 23-37 U/hr.), elimination of neutral red (from 24-38), and gastric gland cells permeability (from 26-37). Titratable acidity and enzymatic activity of the gastric juice remained the same. The hourly secretion of free acid was normalized in several cases; on mechanical stimulation there was an increase of the normal indices of hourly secretion from 39 to 48, and after chemical stimulation, the increase was from 40 to 52.

9062 A METHOD OF STRAIGHTENING GASTRIC FLEXURES. (Rus.) Shniger, N. U.
(Moscow Region Sci. Inst. Roentgen. & Radiol.). Vestn. Rentgen. Radiol. 42(1):22-26, 1967.

Over a 4-yr. period, a clinico-radiological study was performed on 64 patients (42 males, 22 females; 20-68-yr. old) with stable gastric flexure. At radiological examination, complete straightening of the gastric flexure could be obtained in only 14 patients; of the remaining 50 patients, 24 were admitted with suspicion of neoplasm and 18 for perigastritis. At repeat X-ray examination after eating, 52 of 64 showed no gastric deformation, which was preserved or minimized in the remaining 12. In 52 in whom gastric flexure was removed after eating, 10 had a Degree 1 flexure, 31 a Degree 2 flexure and 11 a Degree 3 flexure; 29 had pain in the upper stomach; 22 had regurgitation; 15 had pyrosis; 8, vomiting; 12, sensation of fullness in the epigastrium; 13, nausea, 14, reduced gastric acidity and 7, increased gastric acidity. Careful clinical and radiological examination revealed peptic ulcers in 11, cholecystitis in 6 and suspected appendicitis in 4. In 12 patients with persistent flexures, 5 showed relaxation of the left diaphragmatic cupula of variable degree, and 7 had cancerous tumor and cicatricial ulcerative changes of the stomach. In 5 patients with relaxation of the left diaphragmatic cupula, the most common complaints were regurgitation, sensation of fullness and bulging in the epigastric region. Clinical symptomatology was directly proportional to the degree of the diaphragmatic relaxation and gastric flexure. Gastric cancer occurred in 4 of 7 patients; in 3 of the 7, cicatricial changes were found due to ulcers.

In 6, radiological findings were verified at surgery. In this group the same symptoms predominated which were found in patients with diaphragmatic flexures. Clinical symptomatology was more evident with pronounced flexures. Thus, in the last 2 groups of patients, gastric flexure is also preserved under the conditions of physiological digestion, but the degree of flexure sometimes decreases. In these cases, the clinical picture is conditioned by both the basic disease and by gastric deformation. Two case histories are presented in detail.

9063 DISSEMINATED NECROSIS OF THE GASTRIC MUCOSA OF THE NEWBORN. (Ger.)

Wittstock, G. (Reg. Hosp., Schwerin, Germany). Frankfurt. Z. Path. 76(4):381-387, 1967.

The morphology, histology, age incidence, and correlation with other diseases of disseminated necrosis in the gastric mucosa of infants was examined in 1161 autopsies up to the age of 2 wk. The sharply-defined necrotic areas were small, seldom more than 2 mm across, of a dirty-yellow color; their number varied widely. Conceivably they were very numerous with recognition of only relatively few; they were found in the fundus and body of the stomach, especially in the region of the greater curvature. In many areas the necrosis was limited to the epithelium; in others, the muscularis mucosae and the submucosal connective tissue were involved. Neutrophil and lymphocyte accumulations were sometimes noted. The blood vessels of the submucosa were frequently engorged; vascular erosion was observed. The incidence of necrosis with age was: To 12 hr., 30 of 447, (6.7%); at 12-24 hr., 35 of 209 (16.7%); at 24-48 hr., 47 of 220 (21.4%); at 48-72 hr., 9 of 55 (16.4%); at 3-7 days, 11 of 129 (8.5%); at 7-14 days, 5 of 101 (5%). The incidence of other diseases in 137 cases of disseminated necrosis: 4 with encephalodystrophy (2.9%); 8, brain hemorrhage (5.8%); 66, hyaline membranes (48.2%); 62, amniotic fluid aspiration (45.3%); 33, aspiration of infected amniotic fluid (24.1%); 9, inflammation of the digestive tract (6.6%); 9, miscellaneous (6.6%). The bacteriologic study of infection yielded inclusive results. The etiology of disseminated necrosis of the gastric mucosa is unknown.

9064 GASTRIC SECRETION IN PATIENTS WITH THERMAL BURNS. (Rus.)

Timakov, V. A. (Milit. Med. Acad., Leningrad, USSR). Vestn. Khir. Grekov. 98(1):73-77, 1967.

A tendency toward increased acid secretion and, to a lesser degree, increased enzyme formation by the stomach was found in a study of 181 patients (138 men, 43 women; from 12 to over 45 yr. old) with superficial (70) and deep burns. The frequency and degree of such shifts were incompletely correlated with burn location and depth. Clinically pronounced disturbances of gastric activity were found in only some of the patients. With superficial burns, there was usually a decrease
appetite, moderate thirst and rarely, nausea;
while with deep burns, appetite decreased to co
plete anorexia, plus vomiting and nausea. For
superficial burns, urinary excretion of quinin
increased in 23, decreased in 4 and was normal
18 of 45; resp. values for deep burns were 28,
and 0 in 66 patients studied. Av. values for
quinine excretion when it increased was 268 μg
when decreased it was 42.6 μg and when normal,
81.1 μg. Tubeless analysis showed achlorhydri
in 13 of 40 patients studied. A radiotelemetr
intragastric pH study was performed on 14 pati
with superficial burns and 16 patients with de
burns. The pH was more than 3.5 in half of th
patients with superficial burns of up to 5% of
their surface area, while in patients with bur
of 6-10% of the integument, av. pH was 1.52.
3 of 4 patients with deep burns of less than 5
of the surface area, the pH was approx. 1.5, a
in those with deep burns of more than 10% of
surface area, pH was 1.33. In most patients
during the period of infection resulting from
burn trauma, there was an active secretion of
acid on an empty stomach; its frequency and de
depending upon burn severity. During the peri
of exhaustion due to burn trauma, an active
secretion of acid in the interdigestive phase
was noted in almost all of the patients (8 of
however, the degree of conc. of H ion in gastr
juices was lower than in patients in the postb
infection period. An active gastric secretion
of acid on an empty stomach or after breakfast
was found in 25 of 30 patients studied by radi
capsule. Uropepsin excretion for patients wit
superficial burns increased in 12, decreased i
1, and was normal in 32 of 45 patients studied
the resp. values for those with deep burns wer
24, 3 and 39 of 66 patients studied. For supe
ficial and deep burns, the av. values for norm
uropepsin indices were 48.2 and 37.4 U/hr., re
for increased indices, they were 77.8 and 106.
U/hr., resp. The phenomenon of increased acid
and enzyme excretion by the stomach of patient
with burns is correlated with stimulatory acti
of the products of tissue disintegration on th
gastric glands, such as histamine-like compour
and also with increased activity of the adrena
cortex.

9065 MORPHOLOGICAL CHANGES IN GASTRIC MUC IN PATIENTS WITH THE GASTROINTESTINA FORM OF SALMONELLOSIS AT DIFFERENT STAGES OF T INFECTION. (Rus.)

Sakalinskene, E. M. (2nd
Moscow Med. Inst.). Ter. Arkh. 39(1):37-42, 1

Of 50 patients with gastrointestinal salmonell
and the symptoms of acute gastroenteritis, 20
had a mild course, 27 moderately severe and 3
severe course of the disease. A clinical pict
of an acute inflammatory process infiltrating
deep into the mucous membrane was evident from
the first day of illness and existed when clin
symptoms disappeared. The inflammatory proces
showed simultaneous involvement of tectorial
epithelium, stroma and also the glandular

helium, with symptoms of desquamation and
obiosis. Clinical symptoms disappearance
followed by tectorial epithelium regeneration,
symptoms of necrobiosis and desquamation still
rred in the stromal cells and those lining
glands. These changes were conditioned by
ct action of salmonellae and their toxins on
mucous membrane, and also by hematological
on of these factors. The pathomorphological
ges of the mucous membrane paralleled the
ical symptoms, i.e., the more pronounced the
xication and gastrointestinal symptoms, the
ter the destructive changes in the gastric
us membrane. Patient age was not related to
morphological picture. No difference was
d between bacteriologically confirmed and
nfirmed cases of the diseases.

5 GASTROINTESTINAL BLEEDING: A COMPARISON OF MEFENAMIC ACID AND ASPIRIN. (E.)
ing, A. (Roy. Prince Alfred Hosp., Sydney,
ralia) and K. Bhanthumnavin. Med. J. Aust.
):601-603, 1967.

l blood loss was measured in 53 hospital
ents who were given RBC labeled with ^{51}Cr
μc/10 ml blood). When mefenamic acid [N-
xylyl) anthranilic acid] was given (500 mg
mes a day in 42), blood loss in stools in-
sed from 0.8 to 1.3 ml daily in 26 who passed
than 1.5 ml daily in the control period.
6 who passed more than 1.5 ml daily in the
rol period, blood loss fell from 5.8 to 4.9
aily after mefenamic acid. Controls (11)
ived aspirin (600 mg 4 times daily); here,
daily fecal blood loss rose from 0.7 to 3.5
aily. It is concluded that the capacity of
namic acid to produce intestinal bleeding
light.

7 COLOR PHOTOGRAPHIC EXAMINATION IN CASES OF GASTRIC BLEEDING WITH NORMAL X-RAY
INGS. (Ser.) Gabrielsson, N. (Karolinska
. Stockholm). Lakartidningen 64(24):2465-
, 1967.

tal of 40 cases, 27 men and 13 women (24-89
, av. age 54) with hematemesis and severe
na, the origin of which was not disclosed by
odiagnosis of the stomach, were reexamined
astric color photography; the gastrocamera
used for 36 cases and the combined gastroscope
camera for 4. The gastrocamera can be
led 35°, obviating the dead angles of the
troscope; the combined instruments, like the
troscope, cannot be angled; the camera takes
ictures per load, illuminated by electronic
sh of 1/15 sec. with a fixed focus, taking
rp pictures at distances of 2-10 cm. The
ra is easily introduced into the stomach.
the 40 patients, 24 had hematemesis, 36 melena,
23 had bleeding at time of gastrophotography.
inite diagnosis was made in 31 cases (77.5%);
eding occurred in 12 with mucosal erosion, 9
h ulcers, 7 with varices of the stomach; and
there was 1 with each of the following; polyp, cancer, and suture granulation. The 9 cases with no photographic evidence of cause of hemorrhage also showed no evidence of bleeding at the time of gastrophotography. This technic can reduce the number of X-ray examinations required and increase accuracy of diagnosis.

9068 GASTROCAMERA AND X-RAY INVESTIGATION IN THE DIAGNOSIS OF GASTRIC CONDITIONS. A PRELIMINARY INVESTIGATION OF 102 PATIENTS. (Dan.) Rahbek, I. (St. Elizabeth Hosp., Copenhagen), S. Brünner and J. Mosbech. Ugeskr. Laeg. 129(21):685-688, 1967.

Color pictures of stomach disorders were taken in 102 patients by the gastrocamera at the same time that X-ray examination and X-ray films were made. The diagnostician made full use of color pictures and X-ray material (films and fluoroscopy data). The gastrocamera pictures of 12 patients could not be used because the camera lens became wet with gastric secretion or "red pictures" resulted when the camera was too close to the mucosa. Seven of 13 patients with gastric carcinoma were found by X-ray and 13 of 13 by gastrocamera; the 6 cases of carcinoma, not diagnosed as such by X-ray, were diagnosed as ulcer (4), polyposis (1), and gastritis (1). Among the 77 patients with nonmalignant disorders were 12 who by X-ray were suspected of malignancies (12 tentative false positives), whereas only 3 tentative false positives were reported by the gastrocamera; the same 2 false positives were reported by both methods; diagnosis was definitely made at operation. Of 36 cases of gastric ulcer, 30 were correctly diagnosed by X-ray and 32 by gastrocamera. The diagnosis of gastric carcinoma and the discovery of gastric ulcer can be improved by combining X-ray and gastrocamera studies.

9069 INTRAOPERATIVE BIOPSY OF THE GASTRIC ANTRUM IN LITHIASIS. (Ger.) Stauber, R. (Reg. Hosp., Leoben, Austria). Z. Gastroent. 5(2):79-83, 1967.

Biopsies were obtained at operation for gallstones from 52 patients, 4-5 cm above the pylorus; however, in only 35 of these was the tissue thick enough to differentiate the type of mucosa according to the type of glands. The histologic findings with respect to gastritis were classified by Henning's method. Of the 35 complete biopsies, 13 showed an antral mucosa with typical pyloric glands; 12 were of mixed type, and 10 showed a pure fundic gland structure. In those biopsies having pyloric type glands, mild chronic gastritis was found in 4 and acute exacerbation in 3 of these; moderately severe chronic gastritis in 5, 1 in a stage of acute attack; and 4 with severe chronic gastritis. Each patient with an acute inflammatory attack had a second clinical finding, 2 patients having small duodenal ulcers, 1 stones in the duct, 1 cholangitis, and 1 cholecystitis with empyema. Of the 10 biopsies showing fundic mucosa, 4 had only minimal changes, 5 a moderately severe acute chronic gastritis and 1 was normal (free of any biliary involvement). The 12 mixed or transitional types of biopsies showed 1 normal gastric mucosa, 2 mild superficial gastritis, 5 moderately severe chronic gastritis (4 active, acute) and 4 with severe chronic inflammatory changes; some accompanying conditions were 1 gallbladder to stomach fistula, 1 abscessing cholecystitis, 1 occlusion of the bile duct (stone), 2 acute or chronic pancreatitis and 1 duodenal ulcer. The 17 patients whose biopsies were too shallow for complete evaluation still presented evidence of some degree of gastritis; 3 had chronic gastritis in inflammatory stages; accompanying pathologies were 1 choledocholithiasis with cholangitis, 1 acute pancreatitis, 1 obstructive jaundice (tumor) and 1 severe acute cholecystitis. Of 52 patients, 21 had some degree of chronic gastritis in acute inflammatory stages. Acute, inflammatory stages of gastritis may indicate pathologies of the hepatobiliary, pancreatic, and duodenal regions.

9070 INVESTIGATIONS OF THE EVACUATORY FUNCTION OF THE STOMACH IN HEALTHY INDIVIDUALS WITH THE AID OF A RADIOCAPSULE WITH A pH RECORDER. (Rus.) Votchal, B. E. (Cent. Inst. Advanced Train. Physicians, Moscow) and A. S. Belousov. Ter. Arkh. 39(1):27-32, 1967.

A rhythmic discharge into the duodenum of small portions of gastric material was noted in 37 healthy individuals (25 men, 12 women; 18-35 yr. old) who had been fasting. Depending upon the type of acid secretion in Group 1 (asthenic in 5 of 37, stimulatory in 10 of 37), such discharges were accompanied by pronounced fluctuations of the active reactions of H ions in the duodenum, i.e., pH sharply decreased (to 3.0-4.0) and then rapidly returned to initial indices (7.0-8.0). In Group 2 (inhibitory form of acid secretion in 5 of 37, inert in 7 of 37), discharge of the gastric content did not produce significant changes in duodenal pH; the pH fluctuated between 8.0 and 5.6. In Group 1, during the initial 7-45 min. after consuming bread for breakfast, there was a period of complete inhibition of gastric evacuation followed by a brief (up to 2-3 min.) sequence (of 10-30 sec. duration, and sometimes more) of gastric content discharges which alternated with periods of no evacuation. In Group 2 there was no cessation of evacuation immediately after breakfast. Evacuation from the stomach continued during the initial 10-20 min., and then, with stimulation of the secretory activity of the gastric glands, a period of pyloric closure occurred, followed by a sequence of rhythmic discharges of gastric contents into the duodenum alternating with prolonged (up to 10-15 min.) periods of cessation of evacuation. The apparent dependence of gastric evacuation on the reaction of the gastric secretion confirms the role of the acid factor in the transit of gastric contents into the duodenum.

9071 GASTROSCOPY IN HEMATEMESIS AND MELEN
(Nor.) Myren, J. and P. G. Burhol.
T. Norsk. Laegeforen. 87(9b):835-838, 1967.

In 2 yr. gastroscopy was performed within 24 h
of admission on 77 patients with hematemesis a
melena using Hirschowits' flexible gastroscope
Before the examination each patient received
morphine and atropine, s.c., and the pharynx w
sprayed with a local anesthetic just prior to
insertion of the gastroscope. In 13 subjects
normal gastric mucosa, 6 had never had dyspeps
10 had only 1 hemorrhage, 1 had 2-3, and 2 had
4 or more hemorrhages; av. hemoglobin (in g%)
admission 10.7. In 23 patients with gastritis
and atrophic gastritis: 6 had no dyspepsia; 1
1 hemorrhage; 4, 2-3 hemorrhages; 4, 4 or more
hemorrhages; av. hemoglobin, 11.2. In 16 subj
with gastric ulcer: 7 had no dyspepsia; 11, 1
hemorrhage; 4, 2-3 hemorrhages; 1, 4 or more
hemorrhages; av. hemoglobin, 11.6. Of 3 patie
with gastric tumor: 2 had no dyspepsia; 2, 1
hemorrhage; 1, 2-3 hemorrhages; av. hemoglobin
11.6. Of 14 patients with deformed pylorus:
no dyspepsia; 9, 1 hemorrhage; 5, 2-3 hemorrha
av. hemoglobin 10.9. Of 2 patients with opera
stomach: none had dyspepsia; 2, 1 hemorrhage;
hemoglobin, 9.3. Other conditions included 2
jejunal ulcers and 4 incomplete examinations.
The number of hemorrhages, the gastroscopic
findings, and the amount of gastric distress b
little if any relationship to each other. In 2
of the cases the bleeding source was not disco
by gastroscopic examination. It is suggested
that the combination of X-ray and gastroscopy
might find the bleeding source in more patient
It is concluded that gastroscopy is a good
supplement to X-ray examination.

9072 A MUCOSAL DIAPHRAGM AT THE LEVEL OF
THE PYLORIC ANTRUM IN THE ADULT. (A
ADDITIONAL CONTRIBUTION TO THE ANATOMICAL AND
CLINICAL DESCRIPTION OF THE SAME, BASED ON FOU
SURGICAL OBSERVATIONS.) (It.) Tagliacozzo, S
(U. Rome). Policlinico [Chir.] 74(2):71-99,
1967.

A review of the pathogenesis, frequency of
incidence, clinical diagnosis and treatment of
pyloric stenosis due to the presence of a diap
composed of gastric or duodenal mucosal tissue
includes a report of its occurrence in 4 men,
aged 42-57 yr., in the absence of overt clinic
symptoms or discernible anatomical changes whi
would suggest its existence. In all 4 the
diaphragm contained an orifice which permitted
the passage of food. One of 4 presented with
colic and gastroenteritis, presumably secondar
to lead poisoning of many yr. duration; 1 of 4
each with gastric and pyloric ulcer; 1 of 4, w
chronic indigestion and epigastric pain. In t
first 3 cases, formation of the diaphragm was
thought to be secondary to the presenting cond
above; in the fourth, it appeared to result fr
a torus of pyloric muscle.

ANTISTOMACH ANTIBODIES AND AGING. (Fr.)
Herbeuval, R. (Fac. Med., Nancy, France),
uheille, G. Cuny and A. Haagen. Presse Med.
5):731-735, 1967.

o 1 comprised 41 healthy persons, 22 females
age 23 1/2 yr.) and 19 males (av. age 26
. Group 2 had 108 persons more than 60 yr.
(av. age 76), 69 females and 39 males. The
ers of the second group had experienced
ous diseases and some were suffering from
nic disorders. All subjects were tested for
odies against gastric parietal cells using
indirect immunofluorescent technic of Coons.
y-globulins were separated from human serum
hromatography and inj. into rabbits; the
rescent antibodies were prepared from the
it sera. Pieces of human gastric mucosa of
d Group 0 were treated with the human serum
g tested and then with the fluorescent
ody preparation. The tests were repeated
at gastric mucosa and upon human thyroid
ue. Two males and 1 female in Group 1 were
iers of antibodies against human parietal
s, a percentage of 7.5 for the whole group
n 41). Ten men and 25 women in Group 2, a
entage of 32.4 for the whole group (35 in
, possessed these antibodies; 23 of 57
viduals with different types of anemias
f 7 with Biermer's anemia) carried antibodies
nst gastric parietal cells; 6 of 11 with
rs had antibodies. Within the groups there
no correlation between age and incidence or
ody titer. Apparently healthy individuals
positive for these antibodies. In one case
iermer's hyperchromic anemia with achlorhydria
absence of secretion of the intrinsic factor,
antibody titer was very high. In 64 sera
ned, 14 showed antibodies to both parietal
s and to thyroid gland cells, 13 had antibodies
nst gastric cells only, 21 against thyroid
s only and 16 were without antibodies against
er type of cell; 6 sera possessed an anti-
ear factor associated in 4 cases with the
ltaneous presence of antibodies against both
ric parietal and thyroid gland cells, indicat-
a profound disorder of the immunologic
esses.

INTERRELATIONSHIP BETWEEN THE MORPHO-
LOGICAL AND FUNCTIONAL CHARACTERISTICS
HE STOMACH AND OF CHOLINESTERASE DISTRIBUTION
HE GASTRIC MUCOSA WITH THE PROGRESS OF AGE
ELDERLY INDIVIDUALS). (Rus.) Donskaia, L. V.
ingrad Sanit.-Hyg. Med. Inst., USSR) and
. Smolianskii. Arkh. Pat. 29(3):46-50,
.

d on data obtained from 54 individuals (43
thy elderly persons, 60-88 yr. old, with no
ric disease; 11 young, healthy volunteers,
5 yr. old), 4 groups were found with charac-
stics which define the degree of morphological,
ochemical and functional changes of the
ach. Group 1 represents, morphologically
functionally, the normal stomach; thread-like
cholinesterase was found between the chief and parietal cells and was identified with cholinergic threads in mucosal nerves. Group 2 showed initial gastric changes which were atrophic in character; there was slight thinning of the mucous membrane, slight changes in the chief and parietal cells, moderate weakening of secretory activity (decrease in gastric juice pepsinogen from 1-2.1 g% and of free acid to 10-20 titration U), and a less-pronounced thread net, giving a positive reaction to cholinesterase. Group 3 revealed pronounced atrophic changes, thin and reduced mucosa, a reduced number of chief and parietal cells, a reduced amount of pepsinogen granules in the chief cells, replacement of parts of the glandular parenchyma by connective tissue, initial symptoms of gastric cell metaplasia, hypoacidity (0-10 titration U), a pepsinogen conc. of less than 1.0 g% and cholinesterase in the form of thin, but not interlinked, threads. Group 4 showed markedly pronounced atrophic changes of the stomach, deep dedifferentiation of the chief and parietal cells, a decrease of glands to anadenia or their reorganization into the pyloric or intestinal type, hypo- or anacidity, achylia and the absence of cholinesterase. A decrease in pepsinogen was found in 29 of 36 subjects, a hypo- and anacidic condition in 28 of 36, and enzymatic activity was absent in 34 of 43 older people. Thus, a correlation exists between the presence and character of distribution of cholinesterase in the mucous membrane and the functional and morphological characteristics of the gastric glands. Determination of cholinesterase in the gastric mucous membrane can be used as a histophysiological test which is specific for the morphological and functional peculiarities of the stomach.

9075 CEREAL CONSUMPTION AND GASTRIC CANCER. (E.) Hakama, M. (Finnish Cancer Register, Helsinki) and E. A. Saxén. Int. J. Cancer 2(3):265-268, 1967.

The most striking features in the incidence and mortality of gastric cancer are (1) the great differences between countries (the highest age adjusted mortality is about 10 times greater than the lowest) and (2) a decrease in the decade following 1950 in most countries av. about 15%. These differences are real and not due to variations in standards of diagnosis or treatment; no concurrent increases of tumors other than gastric in the gastrointestinal tract have been noted; no improvement in survival of gastric cancer patients has occurred. The incidence of gastric cancer is higher in lower socio-economic classes, in groups where starchy foods are predominant; in intercountry comparisons national standards of living are correlated with av. per capita income and these are inversely related to the incidence of gastric cancer. The decreased incidence of stomach cancer has been connected with improvement in nutrition. One common characteristic of high incidence areas has been a low consumption of fresh vegetables and fruits and a high consumption of starchy foods. Also, in recent decades the proportion of cereals in the total food consumption has decreased in most countries. If cereal consumption and incidence of gastric cancer are associated, then: (1) the consumption of cereals in countries with high incidence of stomach cancer should be higher than in those with low incidence of such neoplasms and (2) if changes in cereal consumption and changes in stomach cancer occur, although not proportionate or even in the expected direction, there may still be an interrelationship. The changes investigated were in the expected direction and the estimated coefficient of correlation was 0.75 between the variables. With proper adjustment for the latent periods between exposure to the carcinogenic agent and diagnosis of cancer (estimated 20 yr.), the 95% confidence intervals were from 0.41-0.91 and from 0.13-0.91 for age-sex adjusted mortality rates and flour consumption in 16 countries.

9076 SUMMARIZING INDICES FOR COMPARISON OF CANCER INCIDENCE DATA. (E.) Doll, R. (Univ. Coll. Hosp. Med. Sch., London) and P. Cook. Int. J. Cancer 2(3):270-279, 1967.

A method of more concisely expressing the frequencies of cancer is required. In principle, the best comparisons are those between individual sex- and age-specific incidence rates with small age groups; the difficulty with this method is that unless the observations are made on immense numbers (in the order of millions), the rates will be subject to substantial fluctuations due to chance alone. There are many different types of cancer and if 10 or 20 figures have to be kept in mind for each type for each population the task becomes intolerable. The traditional index which is still commonly used is the total incidence standardized for age; different results are obtained depending upon the particular population chosen as standard. There are 3 of these "standard populations", African, World, and European, which show distinct differences with respect to incidence and age; despite these differences, rank order of incidence in 34 different populations for stomach, lung cancer, and leukemia in men and breast cancer in women does not change much with change of population standard. The main differences and difficulties arise from differing frequencies of various specific neoplasms with respect to age, and also the actual age differences among the "standard populations"; for example, the African population is a relatively young one whereas the European (actually based on Scandinavia) is a population of higher av. age. In view of the foregoing it is concluded that: (1) No single index can replace the individual sex- and age-specific incidence rates which are basic. (2) For etiologic studies, age-specific rates can be usefully summarized in 2 indices (a truncated standardized incidence) showing a standardized incidence over a restricted age range, and the other indicating the rate at which cancer increases with age. (3) An appropriate truncated rate for most epithelial cancers for the age range 35-64 yr., using wt. of 6, 6, 6, 5, 4, and 4 for the individual 5-yr. age groups (derived from Segi's World Standard Population). For other cancers, age ranges of 0-14 yr., and of 0-44 yr. would be more suitable with wt. of 12, 10, and 9; and 12, 10, 9, 9, 8, 8, 6, 6, 6 for the corresponding 5-yr. groups. (4) An indication of the general character of a given set of incidence data may be obtained by calcul ing the ratio of the rates at 55-64 yr. and at 35-44 yr. for a combined group of cancers which normally increase rapidly in incidence with age

9077 HISTOGENESIS OF GASTRIC CARCINOMA. (Rus.) Vasilenko, I. V. (Donets Med. Inst., USSR). Arkh. Pat. 29(3):31-36, 1967.

In a study on 62 stomachs with cancerous tumors 2 histogenetic types of carcinoma of the stomac were found: Group 1, cancer originating from mucoid cells of the gastric fossa region and th cervix of stomach glands; and Group 2, cancer originating from intestinal epithelium which developed in the stomach as a result of metapla Cancer from mucoid cells had an undifferentiate micro- and polymorphocellular histological stru ture, with a larger amount of mucoid granules i the cytoplasm and in individual cricoid cells. Cancer from intestinal epithelium was character by a glandular structure (with large glands), a high and cylindrical epithelium, large and hype chromic nuclei, the absence of secretion and by the presence of goblet cells; in rare cases of collodial cancer, its origin from glandular can was clearly evident. In Group 1, the av. age of patients was 47 yr.; in Group 2, 58 yr. In Group 2, exophytic tumor growth in the form of nodules or ulcers with spindle-forming ends was evident; in Group 1, in 1 case there was a flat nodule with clear ends, while the remaining tum was infiltrative in form. All of the cancers i Group 2 had a small-moderate content of stroma and no scirrhus, while in Group 1, 16 had a scirrhous character and 4 had a moderate amount of stroma. Cancer cells from Group 2 had a hig content of RNA, while cells from Group 1 cancer usually had a low-moderate amount of RNA. In Group 2, intestinal metaplasia was highly pronounced in 11 and moderately pronounced in 10; in Group 1, highly-pronounced intestinal metaplasia was found in 1 case, a moderately-pronounced metaplasia in 9, and a slight-absent amount of metaplasia in the remaining cases. Marked differences of these 2 types of cancer are conditioned by their different histogenesis

9078 THE COURSE OF GASTRIC EPITHELIOMA IN RELATION TO HISTOLOGY. (Fr.) Razem P. (City Hosp., Lille, France) and C. Gautier-Benoit. Ann. Chir. 21(3-4):154-159, 1967.

Of 830 stomach tumors, 489 were classified histologically; 470 of these were epitheliomas of various types (differentiated or glandular

fferentiated or trabecular 62; linitis 62;
id 43; Lieberkuhn Type 2). Malignant ulcers
present in 18 cases. The lower, middle and
r portion of the stomach was involved in 254,
and 90 cases, resp.; the entire stomach was
lved in 30 cases. Differentiated epithelioma
malignant ulcers were more frequent in the
r portion of the stomach (64.67% and 68.41%,
., of cases); the other tumor types showed
pprox. equal distribution. Perforation was
most frequent in patients with mucoid epi-
iomas (3 cases = 6.97%); hemorrhage was more
uent in patients with undifferentiated (7
s = 11.28%) and mucoid epitheliomas (4
s = 9.3%). Lymph node invasion was most
uent in patients with mucoid tumors (71%) and
t frequent in the presence of malignant ulcer
); local invasion was present in 20-21% of
patients with mucoid or differentiated tumors,
ared to 10-12% of patients with tumors of
r types. Metastases were most frequent in
ents with mucoid or undifferentiated tumors
and 16%, resp.) and least frequent in cases
initis (5%). The growth rates of these
rs appeared to be about the same, however.
ignificant age differences were noted. The
. survival rates in patients with malignant
rs, linitis, differentiated or undifferentiated
helioma, and mucoid epithelioma were 36%,
19%, 17%, and 12%, resp. Analysis of sur-
l rates according to the stage of disease
) was not possible in several groups because
were too small for statistical evaluation,
the av. survival time in 52 patients with
e 3-5 disease undergoing laparotomy only was
r 5 mo. regardless of tumor type. Following
gastrectomy, best results were seen in patients
Stage 2 differentiated or undifferentiated
helioma (av. survival times were 83 and 57
resp.). The av. survival time in patients
mucoid epithelioma or linitis was better
owing 80% gastrectomy (44.6 and 36.5 mo.,
., in Stage 3) than after 67% gastrectomy
7 and 3.7 mo., resp., in Stage 1). Total
rectomy (performed of necessity or as a
entive measure) gave best results in patients
differentaited epithelioma, especially in
e 2; in the other groups, av. survival times
about the same as after partial gastrectomy.
nectomy worsened the prognosis of 80%
rectomy in all patients except those with
tis. Chemotherapy with 5-fluorouracil (750-
mg/day i.v. to leukopenia) or cyclophosphamide
some cases) in a single postoperative course
not seem to modify the evolution of the
ase after 67% or 80% gastrectomy in any tumor
.

THE VALUE OF LACTIC OXIDOREDUCTASE
ACTIVITY DETERMINATION IN THE GASTRIC
ENTS AFTER HISTAMINE STIMULATION IN THE
NOSIS OF GASTRIC CANCER. (Pol.) Cieślińska,
lst Inst. Intern. Dis., Acad. Med., Szczecin,
nd). Wiad. Lek. 19(19):1539-1542, 1966.

6 controls the L-lactic acid oxidoreductase activity in the gastric content was 0.6-22.1 U with a mean of 6.2 U; in the serum 5.5-11.5 with a mean of 8.5 U. In 20 duodenal ulcer patients: gastric contents 2.8-20.6 U, mean 9.1 U; in serum 3.3-11 U, mean 6.9 U. In 20 gastric ulcer patients: in gastric content 1-42.4 U, mean 10.2 U; in serum 0-15 U, mean 7.5 U. For 16 gastric carcinoma patients: in gastric content 0-161 U, mean 23.9 U (patients with high activity showed widespread neoplastic changes, mainly adenocarcinoma); in serum 5.7-25 U, mean of 10.2 U. In the control group the mean values of activity were higher in the serum than in the gastric content, while this situation was reversed in patients with duodenal ulcers, gastric ulcers and gastric carcinoma. The mean activity of this enzyme in patients with gastric carcinoma surpassed the values obtained in patients with gastric or duodenal ulcers. However, no distinct differences were seen between the number of patients with high enzyme activity in the carcinoma group when compared to the ther groups. It is therefore concluded that L-lactic acid oxidoreductase determination cannot be used for differential diagnosis of gastric carcinoma and gastric ulcer.

9080 TREATMENT OF DUMPING SYNDROME WITH SEROTONIN ANTAGONISTS. CLINICAL OBSERVATIONS. (It.) Camarri, E. (U. Siena, Italy), G. P. Bassi and P. F. Bayeli. Gazz. Med. Ital. 126(3):91-96, 1967.

N-Carbobenzyloxy-1-methyldihydro-L-lysergamine (FI 6337) was admin. p.o. (total dose 24-1380 mg) to 24 patients (21 men and 3 women; age 28-74 yr.) with postgastrectomy dumping syndrome. Gastrectomy (Billroth II) had been performed 1-17 yr. (av. 6.3 yr.) previously. Results were classified as excellent in 10 patients (41.6%), good in 8 (33.4%), slight in 3 (13.5%), and poor in 3 (13.5%). Among the symptoms which showed improvement following FI 6337 therapy were epigastric wt., abdominal discomfort, vomiting, diarrhea, yawning, aerogastria, sleepiness, headache, and cyanosis of the upper extremities. No side effects were observed in 20 of 24 (83.3%) patients; others showed paresthesia (3), precordial pain and hypotension (1), or hypotension with tachycardia and fainting (1); treatment was suspended in 1 patient. In 15 patients in whom dumping syndrome had been induced experimentally (100 g of glucose in 500 ml H_2O p.o.), the i.m. admin. of FI 6337 (2-4 mg) caused marked (2) or good (6) regression of symptoms, slight improvement (2), no change (4), or worsening (1). Hematocrit, blood sugar, and blood K values did not change significantly in patients with experimentally-induced dumping syndrome. The results confirm that serotonin is one of the major humoral factors responsible for postgastrectomy dumping syndrome. However, the failure of some patients to respond to serotonin antagonists indicates that not all postprandial disturbances following gastrectomy are due to the release of serotonin.

9081 ALTERATION OF THE EXCRETORY FUNCTION OF THE PANCREAS AFTER JEJUNOGASTROPLASTY (REDUODENIZATION) IN THE DUMPING SYNDROME.

(Rus.) Volobuev, N. N. (Crimea Med. Inst., Simferopol, USSR). Khirurgiia (Moskva) 43(3):52-56, 1967.

During 1959-1965, jejunogastroplasty was performed on 80 patients (65 men, 15 women; from less than 30 to over 60-yr. of age) with severe dumping syndrome which had developed immediately or 20 yr. after resection for gastric or duodenal ulcers (in 75), gastric polyposis (in 4) or gastric carcinoma (in 1). Only 1 of 80 died due to faulty sutures of the interintestinal anastomosis. Of 72 observed for 6 mo.-5 yr. after jejunogastroplasty, the dumping syndrome disappeared immediately or at various periods after surgery in 66, with no improvement occurring in 6. Of 59 studied before jejunogastroplasty, a normal conc. of enzymes in the intestinal juice was found in 1 and a decreased amount in 6; normal variants of secretion curves were found in 5, abnormal function of the pancreas in 47, disturbed separation of trypsin in 41, of lipase in 35, of amylase in 11 and a high amylase conc. in 39; creatorrhea occurred in 40, steatorrhea in 32, amylorrhea in 16 and the content of fat in the feces av. 17.6%. After jejunogastroplasty (3 mo.-5 yr.) all 50 subjects showed improvement and even normalization of the indices of pancreatic secretion; 41 had normal variations of dynamic secretion curves, 8 had an abnormal function of the pancreas and a normal coprogram was found in 50 of 54 subjects studied; the content of fat in the feces av. 5.4%, and moderate digestive disturbances were found in 4. Only 1 patient had an exacerbation of pancreatic secretion, after a period of improvement. A wt. increase of less than 5-34 kg after jejunogastroplasty was noted in 66. Improvement was dependent upon the length of time since reconstructive surgery. One case history is presented in detail.

9082 CHANGES IN ABDOMINAL ORGANS IN THE DUMPING SYNDROME.

(Rus.) Samokhvalov, V. I. (Milit. Med. Acad., Leningrad, USSR) and S. A. Kalashnikov. Klin. Med. (Moskva) 45(2):31-35, 1967.

A total of 125 patients had gastric surgery 1-10 yr. previously for gastric or duodenal ulcers (102) or polyposis or cancer (23); of this total, 49 had reconstructive surgery for severe dumping syndrome, 24 for afferent loop syndrome, 24 for peptic ulcer, 4 for postsurgical alimentary dystrophy and 24 for severe postoperative disturbances (biliary, gastric, duodenal and pancreatic fistulas, gastric and duodenal-stump tumors and gastrointestinal bleeding of unknown causation). A diffuse enlargement and induration of the liver was found in 4, pronounced liver cirrhosis in 1, enlarged liver in 2 and dense liver in 1. Biopsy material showed no morphological changes in 32 of the 62 studied; 8 showed slight edema of the periportal layers with circular sclerosis of the bile-duct walls; 17 exhibited edema of the periportal layer with lymphoid-ce lar infiltration, while 5 had inflammatory in tration of the liver stroma. A similar histo picture of liver structure appeared in the co group (22 patients with laparotomy for variou diseases of the abdominal organs). There was increase in the frequency of liver cirrhosis to the passage of time after a Billroth II gastrectomy. There was no basic difference i the frequency of changes associated with the various types of postoperative disturbances, no specific histochemical changes were eviden in the livers of patients with various types postsurgical disturbances. There was an incr frequency for tense or atonic gallbladder in patients with dumping syndrome, and especiall in those with inlet loop syndrome, more than those with other types of disturbances. Incr induration of the pancreas in patients with p operative disturbances could not be demonstra The duodenum and afferent loop in most of the patients had decreased tonus and atrophic wal while changes in the efferent loop were more pronounced. Such changes were found in those patients with the dumping syndrome and the afferent loop syndrome. There were no cases jejunitis. These changes in the small intest reflect a compensatory process occurring in t intestine in response to altered conditions o digestion after gastrectomy.

9083 THE ROLE OF HEPATOPANCREATODUODENAL SECRETION IN THE PATHOGENESIS OF TH DUMPING SYNDROME.

(Rus.) Markin, S. P. (Cen Inst. Postgrad. Med., Moscow) and I. V. Ognev Klin. Med. (Moskva) 45(2):49-57, 1967.

Various studies were conducted on 22 patients (16 men, 6 women; av. age 40 yr.) who had und gone (av. 3.8 yr. previously) a Billroth II gastrectomy; studies included laboratory, cli X-ray tests as well as stimulation of secreti from the hepatopancreaticoduodenal complex an excretion of enzymes by the pancreas. These patients exhibited 3 forms of the dumping syn Group 1, 7 patients, a severe or decompensate form; Group 2, 8 patients, a moderately sever or subcompensated form; and Group 3, 7 patien with a mild or compensated form. In Group 1 patients, dumping syndrome seizures developed not only after feeding of carbohydrates and milk, but also after an excess of liquid food (cold or warm). In Group 2, dumping syn seizures occurred after feeding with easily assimilated carbohydrates and neutral fats. Group 3, dumping syndrome seizures rarely occ this group exhibited a high sensitivity towar milk, which caused dumping syndrome seizures. In all 22 of the patients, the dumping syndro had already developed during the early postop tive period. In patients who developed the dumping syndrome after a Billroth II gastrect the processes of gastric juice and enzyme sec tion after the admin. of stimulants (hyperton soln. of glucose, milk, fats) were markedly disturbed when compared to those of controls

ch comprised 11 healthy persons). Stimulation
nese processes during the first hr. of observa-
was followed by a rapid exhaustion of secre-
ability; a latent period was lacking, the
ific activity of most of the enzymes was
eased on an empty stomach and changes were
ific for each group. In Group 2, exocrine
vity of the pancreas was increased and the
ion to enzyme secretion was markedly labile,
apparently indicated an increased excita-
y of the secretory apparatus of the pancreas.
. of stimulants caused a significant decrease
ylolytic activity during the initial period
servation, which probably explains the
ity of the form of dumping syndrome which
induced by glucose. In Group 3, the quality
absolute amount of juice and enzymatic secre-
differed little from that in the controls;
an increased secretion of lipolytic enzymes
rred after admin. of stimulants in the patients
his group. Thus, in the dumping syndrome which
ows a Billroth II gastrectomy, depending upon
clinical picture and the duration of the
operative course, disturbance of the exocrine
vity of the hepatopancreaticoduodenal system
rred, which is largely connected with the
rity of the symptoms of the postoperative
romes.

THE MORPHOLOGICAL PICTURE OF THE JEJUNAL
MUCOUS MEMBRANE AFTER BILLROTH-II
ATION. (Rus.) Salupere, V. P. (Tartu U.
., USSR). Khirurgiia (Moskva) 43(3):57-61,
.

histological state of the jejunum was studied
0 patients (21 women, 19 men; 20-60 yr. old)
had undergone a Billroth II gastrectomy 14
-10 yr. previously for gastric ulcers (10),
enal ulcer (18) and gastric tumors (12). A
nal biopsy was obtained from 40 of the patients,
a biopsy of the mucous membrane of the gastric
p from 20 of the 40 patients. A normal jejunal
us membrane was found in 31 patients, and 9
bited villous atrophy of the jejunal mucous
rane; in 6 of the latter the changes were
ht and were initially expressed by a decrease
he amount of villi. The thickness of the
us membrane in villous atrophy was 623 μ,
that of normal mucous membrane was 788 μ;
ver, this difference was not a reliable index.
illous atrophy the correlation of villi to the
dual mucous membrane was 2.8:1, and in
als it was 3.9:1; this difference was
fied. The composition of cellular infiltra-
in villous atrophy was as follows: lympho-
s, 637; neutrophils, 5; eosinophils, 41;
ma cells, 304 and mast cells, 13; the respec-
values for normal mucous membrane were 689,
0, 195 and 41. The difference between normal
atrophic mucous membrane was verified only
plasma and mast cells. In 20 patients who
both a gastric and a jejunal biopsy, the
us membrane of the gastric stump was atrophic
9 of 20, while the mucous membrane of the
num was normal in 15 of 20. The length of postoperative recovery had no effect on the structure of the jejunal mucous membrane. The arrangement of mucopolysaccharides in normal and atrophic mucous membrane was identical. Therefore, the protective qualities of the mucopolysaccharide components of the jejunal mucous membrane may be one of the factors which conditions preservation of normal structure of the jejunal mucous membrane for a long period after surgery.

9085 CLINICO-MORPHOLOGICAL INVESTIGATIONS IN PATIENTS AT REMOTE PERIODS AFTER REPAIR OF THE STOMACH WITH AN INTESTINAL GRAFT. (Rus.) Androsov, P. I. (Surg. Clin., Acad. Med. Sci., Moscow), A. M. Akimov, V. V. Balashova and A. M. Suslov. Khirurgiia (Moskva) 43(3):61-69, 1967.

A total of 61 patients (40 men, 21 women; 36-62 yr. old) were gastrectomized (total gastrectomy in 30, total-subtotal in 22 and subtotal in 9) for gastric cancer (51), benign gastric neoplasms (2), cicatricial gastric stenosis after acid burn (1) and gastroduodenal ulcers (7). A gastric prosthesis was formed in these by transplant of the large intestine (28) or small intestine (33); endoscopic examination was performed on 12 patients and morphologic studies of the intestinal transplant made on 18, both at periods of 4 mo.-9.5 yr. after operation. During the early postoperative period, endoscopic studies revealed inflammatory changes on the superficial mucous membrane of the anastomosis and intestinal transplant; during later periods, atrophy of the mucous membrane of the transplant and gastric stump, and individual examples of functional-morphological reorganization, were noted. During a long postoperative period in the small-intestine transplant, the amount of mucus on the mucous membrane surface was decreased, the latter had a dry appearance; and the amount of mucus in the large-intestine transplant increased. Morphological examination of the small-intestinal transplant in 8 patients revealed progressive atrophy of the mucous membrane with stromatic fibrosis and deformation, and various-sized villi; in addition, there were massive round-cellular infiltrations with a large amount of plasma cells, and in some cases, lymphoid folliculi with light centers of multiplication observed among such infiltrations. Venous stasis occurred plus a progressive decrease of mucus-forming (goblet) cells, especially in the apical portions. Study of the large-intestinal transplant in 7 patients showed increasing fibrosis of the submucous layer, decrease of lymphoid follicules and hyperfunction of the mucus-forming cells; the latter increased in proportion to the length of the postoperative period. At later periods, there was a massive layer of mucus on the surface of the transplant, and mucous degeneration of the large-intestinal glands. The gastric stump in 3 patients showed progressive atrophy of the mucous membrane of the cardia and a decrease in the number of glands; there were round-cell infiltrates, with eosinophils and plasma cells, in the stroma; also noted were fibrous submucous layers with dense round-cell infiltrates and venous hyperemia, and antralization of the mucous membrane. A general clinical study was made on 42 patients 15 days-9.5 yr. after surgery; in the early (up to 3 wk.) postoperative period there mild symptoms of dyspepsia, decreased tonus of the small-intestinal transplant, frequent, irregular segmental and pronounced pendular movements. Motor function of the large-intestinal transplant was characterized by slow peristaltic contractions of small amplitude. Long-term studies revealed utilization of reservoir, motor and evacuation functions by both types of intestinal transplant. In patients gastrectomized for cancer, hemopoiesis and serum proteins were somewhat decreased while all biochemical indices were normal in patients gastrectomized for ulcers. In cancer patients, postoperative wt. increase av. 5-7 kg, and in ulcer patients, it was 10-15 kg. Subjective clinical improvement occurred in patients with large-intestinal transplants. The amount of mucus in small-intestinal transplants was significantly lower than in large-intestinal transplants. After total and subtotal-total gastrectomy, the free and bound acid was zero, and total acidity 8-10. Only during the early postoperative period did the coprogram reveal a slight decrease in fat digestion.

9086 LATE POSTPRANDIAL HYPOGLYCEMIA OF THE GASTRECTOMIZED PATIENT AND THE PERIPHERAL UTILIZATION OF GLUCOSE.

(Fr.) Longueville, J. (St. Pierre U. Clin., Louvain, Belgium), J. De Plaen, R. Vlassembrouck and R. De Meyer. Acta Gastroent. Belg. 30(3):185-208, 1967.

Of 51 patients (5 women), 29 were gastrectomized. Of the latter, 12 had the typical dumping syndrome; 6 (less than 120 mg% glucose) had an atypical syndrome which could be provoked by oral loading resulting in hyperglycemia and dumping 90 min. later; 11 other gastrectomized patients were diabetics (more than 120 mg% glucose) having the same type of dumping 90 min. after provocation. Among 11 cases with gastroduodenal ulcers 5 were diabetic; 6 patients had spontaneous hypoglycemia; 6 patients were normal with respect to carbohydrate metabolism. In the analyses, oral and i.v. tolerance tests were used as well as a tolerance test with i.v. glucose after stimulation of release of insulin by oral intake of glucose. After various tests it is concluded that gastrectomy caused changes in the body wt., the surface area of the body, and the glucose space, and in the relationships among these factors which made the gastrectomized patients abnormal. The gastrectomized patients fell into 3 groups. Those who had late postprandial hypoglycemia had a normal glucose assimilation, fasting as well as after oral glucose intake; the fasting glycogenolysis was increased. The diabetic gastrectomized patients showed reduced glucose assimilation in all conditions; fasting glycogenolysis was also reduced. Those with hypoglycemia, free of the dumping syndrome, had a diminished glucose assimilation fasting and after oral glucose loading; glycogenolysis was normal under fast conditions. Gastrectomized patients whose ch difficulty was hypoglycemia did not release excess amounts of insulin as occurred in spon neous hypoglycemia. Patients with peptic ulc showed 2 different patterns: Those who were diabetic had a decreased glucose assimilation with increased fasting blood sugar levels. T were those whose fasting glucose assimilation fasting glycogenolysis and glucose space were increased while their body wt. and surface ar decreased; glucose assimilation after ingesti of glucose was only slightly increased.

9087 STUDY OF THE GASTRIC STUMP: COMPAR OF GASTROSCOPIC, BIOPSY AND RADIOLO EXAMINATIONS.

(It.) Saracco, C. (U. Turin, Italy), F. Balzola and V. Lombardo. Minerva Gastroent. 12(4):141-145, 1966.

Among 105 men and 15 women developing renewed gastrointestinal symptoms 4 mo.-24 yr. after gastric resection, 90 had been operated upon duodenal ulcer, 15 for gastric ulcer, 14 in t absence of confirmable diagnosis and 1 in the presence of a gastric neoplasm. The age rang at the time of surgery was 24-63 yr., with ma incidence in the third decade of life. Sympt responsible for renewed consultation included epigastric distress (84 cases), wt. loss (50) hemorrhage (36), asthenia (34), vomiting (30) anorexia (31), heartburn (26), diarrhea (12) dumping syndrome (5). A table is presented o X-ray and gastroscopic diagnoses, plus the nu of cases in which these agreed, as follows: normal = 36, 31 and 10, resp.; gastritis, sto tis or jejunitis = 18, 53 and 4, resp.; ulcer tion of the gastric stump = 20, 6 and 4, resp suspected ulceration = 14, 0 and 0, resp.; ca of the stump = 2, 11 and 1, resp.; suspected cancer = 7, 0 and 0, resp.; perivisceritis = 6 and 3, resp.; jejunal ulcer = 1, 0 and 0, r operative artifacts = 0, 6 and 0, resp.; othe 10, 7 and 0, resp. Among 59 patients who als underwent biopsy of the mucosa of the gastric stump, biopsy confirmed X-ray findings in 50% of the cases; confirmed gastroscopic findings in 66%. Among the total of 120 patients, pat logical changes involving the gastric stump w confirmed in 93.5% of the group, but changes demonstrable by 2 or more methods in only 34% It is concluded that all 3 methods should be employed whenever possible.

9088 EFFECTS OF EXPOSURE, FREEZING, AND RADIATION ON EXPLANTED GASTRIC MUCO

(E.) Harata, N. (U. Chicago, Ill.), C. Vokin and D. J. Ferguson. Amer. J. Dig. Dis. 12(7) 674-684, 1967.

Canine (fundic) gastric mucosa was explanted onto the abdominal wall in 3 vascularized pie each approx. 3 cm in diameter; some explants covered with plastic or skin, and others rema

osed. Explants which were covered with skin
ained nearly normal histologic features and
reted acid. Explants covered with plastic
e less well preserved, and those without cover
t all parietal and chief cells. Parietal cells
ppeared in undifferentiated mucosa approx.
k. after recovering the explant. All explants
ntained a healthy-appearing mucosa. Removal of
stic covers was followed within 6 hr. by loss
acid-secretory function, possibly as a result
lowered temperature. Measured freezing of 1
lant and irradiation of another were compared
h controls in the same dogs, with and without
n cover; ulcers were made with a punch, and
ling time was noted. Acid secretion in response
histamine was measured qualitatively. Both
adiation and freezing temporarily eliminated
d secretion and produced long-lasting changes
the mucosa; ulcer healing time was increased.

9 LABELLED FLUOROBORATE IN THE STOMACH
OF RATS. (E.) Matthews, C. M. E.
mmersmith Hosp., London). Nature (London)
(5091):933-935, 1967.

rier-free ^{18}fluoroborate, dissolved in saline,
inj. i.v. into rats. Some received 4.8 mg
chlorate i.p. 20 min. before inj. of label;
e received carrier fluoroborate. Rats were
led at intervals after inj., and organs were
oved, weighed and counted. Tumors were RIB5
SBS1 fibrosarcomas previously implanted s.c.
the flank. Conc. of label in most organs
alleled the body av., but were higher in the
mach. Perchlorate reduced uptake, but addition
carrier fluoroborate had no further effect.
rier fluoroborate without perchlorate also
uced uptake, but a higher conc. was required
give the same degree of reduction as with
chlorate alone: 2.3 mg of carrier reduced
ake at 1 hr. to 60% of that for carrier-free
erial; 5 mg carrier reduced it to 30%. It is
gested that fluoroborate is conc. in the stomach
the same way as iodide. Perchlorate had no
nificant effect on conc. in tumors and brain
tumor/brain ratio. Expected radiation doses
ds/mc) to humans were: gonads, male 0.060,
ale 0.071; stomach 0.57; av. whole body 0.048.
mach uptake increased linearly with time up to
r. and remained constant. It is concluded
t labeled fluoroborate is not as useful for
in scanning as was suggested, but it still
pares favorably with the other position emitters.
earlier estimate of 13.3 for the A factor is
uced to 10.9, assuming perchlorate will be
en and will produce the same blockage of uptake
human stomachs as in rats. The use of carrier-
e fluoroborate for stomach scanning is sug-
ted.

0 SURVIVAL IN RATS AFTER GASTRECTOMY OR
GASTRIC BYPASS. (Fr.) Lambert, R.
ouard Herriot Hosp., Lyon, France), F. Martin
F. Descos. Arch. Franc. Mal. Appar. Dig.
3):141-162, 1967.

To determine whether the mere presence of the stomach indirectly influences nutrition by means of its vascular connections, the effect of gastrectomy and gastric bypass was studied in rats; correcting the nutritional deficiency following this surgery was also studied. A total of 379 white rats were divided into 3 groups: a) 54 males as control; b) 105 males with total gastrectomy, subdivided into treated and untreated groups; c) 65 females and 155 males both with gastric bypass, also subdivided into treated and untreated groups. Even though the bypass seemed to be less mutilating and better tolerated, both surgical procedures led to superinfection. After esophagojejunostomy, lifespan was shortened, very few rats surviving 12 mo.; preoperative wt. was not regained; anemia occurred from the third mo. on (dropping from the normal 10 million ml^3 to between 6-7 million). After esophagoduodenostomy, tolerance was better for 6 mo., with more survivors; the postoperative wt. slightly exceeded the preoperative, anemia was less, but after 6 mo. the condition worsened. After gastric bypass, the results were comparable with those after gastrectomy. It was noted, however, that the females tolerated the intervention better, especially with respect to wt. Results of treatment to counteract physiopathologic sequelae were similar in both gastrectomized rats and in those with a gastric bypass, although the correction of just one of the pathologic effects improved the gastrectomized animal only temporarily, but led to more improvement in the animal with the bypass. It is concluded that there was no evidence for any indirect activity of the stomach contributing to nutrition through its vascular connections.

9138 USE OF AN ANTIPERISTALTIC COLONIC SEGMENT INTERPOSITION TO REDUCE SMALL INTESTINE MOTILITY FOLLOWING EXTENSIVE RESECTION. (A PRELIMINARY COMMUNICATION). (Fr.) Vayre, P. (Vaugirard Hosp., Paris), J. Hureau and R. Soyer. Ann. Chir. 21(9-10):521-526, 1967.

Antiperistaltic interpositions were tried in dogs in order to retain the contents in the small intestinal segment for periods sufficient for absorption through the reduced surface area. The dogs were given supportive treatment for 1 wk. prior to surgery including admin. of antibiotics; during operation they received i.v. glucose. The first type of colonic interposition was the right oblique angle jejuno-colic in reverse direction (antiperistaltic) with retention of the ileocecal valve; the other anastomoses in this type were colo-ileal and colo-colic. The second type was like the first with removal of the ileocecal valve and an anastomosis on the anterior face of the cecum. The third type utilized the ceco-appendicular region rotated 180° with jejuno-cecal and appendiculo-colic anastomoses. Control dogs underwent corresponding enterectomy only. Twelve of the first type, the colonic transplant, were prepared; 3 died in a few days, 1 from hemorrhage and 2 with a broncho-pulmonary syndrome. The remaining 9 animals survived and were kept under observation for 4-6 mo. Postoperatively there were 3 stages. During the first 8 or 10 days the animals were asthenic and anorexic with abundant soft stools; in the next 5-6 days the dogs underwent a period of adaptation with more normal digestion and less disturbed transit; the stools, 5-6/day remained soft. At the end of 1 mo. the animals were in good condition having regained their original wt. and vigor. The stools of 4 were completely normal; those of the others remained somewhat soft. The blood picture was entirely normal in all components. The progress of contrast medium was followed; radioisotope studies of protein and fat metabolism were made and were normal. The control animals lived for a wk. on the av.; they would not accept food and drank great quantities of water, and died of cachexia and profuse diarrhea. It is concluded that interference with the ileocecal valve has serious consequences, especially with subtotal enterectomies.

9139 EVALUATION OF THE EXCHANGEABLE POTASSIUM POOL AFTER ILEOSTOMY. (EXPERIMENTAL STUDY.) (It.) Balzola, F. (U. Turin, Italy), S. Lamarca, G. Giribone, A. Mussa and A. Pera. Minerva Gastroent. 12(4):127-129, 1966.

In rabbits (approx. wt. 2 kg at the start of the experiment) and subjected to ileostomy, inj. of ^{42}K (60 c, i.v., 18-72 hr. after surgery) was followed by determinations of 12- and 24-hr. urinary excretions of the isotope and estimations of the available pool of exchangeable K. Only 19 of 60 animals survived to the fourth day; none survived to the fifth. Among 5 of the 19 operated animals which survived to day 4, the estimated pool of exchangeable K on the third day ranged from 49-102 U/kg.; among 5 controls it ranged from 110-197 U/kg. Among 14 of 41 operated animals which died within 48 hr., the estimated pool on the first day ranged from 41-122 U/kg, as compared to 163-290 U/kg among 10 controls. No tabulations are given for the remaining animals among either the short-term relatively long-term survivors of surgery. It is concluded that the electrolyte deficit whic followed ileostomy became irreversible in a ve short time, in the absence of substitution therapy, thus precluding the animals' survival

9140 COMPARATIVE STRENGTH OF INVERTED, EVERTED, AND END-ON INTESTINAL ANASTOMOSES. (E.) Loeb, M. J. (Minneapolis Veterans Hosp., Minn.). Surg. Gynec. Obstet. 125(2):301-304, 1967.

Anastomoses (4) were performed on mongrel dogs 2 in the jejunum just beyond the ligament of Treitz and 2 in the ileum approx. 6 inches fr the cecum. Four groups of 7 dogs each were tested as follows: Group 1, everted vs. inver anastomosis (sacrifice and testing performed the third postoperative day); Group 2, everte vs. inverted anastomosis (sacrifice and testin on the seventh postoperative day); Group 3, inverted vs. end-on anastomosis; and Group 4, end-on single layer vs. inverted 2-layer anastomosis tested at 3 days. No dogs died from leakage of the anastomosis. At 3 days, mean bursting force of the jejunal inverted anastomosis was 4.20±1.7 dynes/cm compared to 1.41±0.84 for jejunal everted anastomosis. T inverted ileal anastomosis was similarly stro 2.73±1.43 dynes/cm vs. 1.82±1.27 dynes/cm for the everted. At 7 days postoperatively, inverted anastomosis was again superior, 5.08±1. dynes/cm vs. 3.22±2.02 dynes/cm in the jejunu and 4.95±2.37 dynes/cm vs. 2.94±2.20 dynes/cm the ileum. In the jejunum, inverted anastomos av. 2.46±1.67 dynes/cm while end-on av. 2.25± dynes/cm; in the ileum, inverted anastomoses 1.78±0.88 dynes/cm and end-on anastomoses 1.52±0.78. Comparison between end-on anastom and stardard 2-layer inverted anastomoses sho that in the jejunum, the mean bursting force 2±1.37 dynes/cm for the end-on anastomoses an 3.37±1.13 dynes/cm for the 2-layer inverted anastomoses. The ileal anastomoses av. 1.09± dynes/cm for the end-on and 2.32±0.91 dynes/c with inverted 2-layer anastomoses. Thus, the strongest union proved to be the standard 2-layer inverted technic. One-layer inverted end-on anastomoses, although slightly weaker, were satisfactory because of ease of technic, less compromise of blood supply, and a larger lumen at the site of anastomosis. No significant difference was noted between the 1-layer inverted and end-on method. Everted anastomos

weakest and, although feasible, are not
ommended for general use.

SEGMENTAL SURGERY OF THE TERMINAL ILEUM OR THE RIGHT COLON FOR BENIGN LESIONS.

) Popesco-Urlueni, M. *Lyon Chir*. 63(3):
373, 1967.

ctions of the terminal ileum were done for a
er of different reasons; occlusion, intussus-
ion, stenosis, etc. Where complete tran-
ion was necessary, in 2 cases the continuity
he intestine was re-established by end-to-end
l anastomoses and 5 times by ileocecal end-
ide anastomoses. Ten resections of the
cecal ascending regions were accomplished for
ulus, tumor, etc. Continuity was re-established
leo-ascending cecal anastomosis or end-to-end
tomosis. One resection of the ascending
m and 2 resections of the hepatic angle were
owed by re-establishment of continuity by
to-end cecocolostomy, called transplantation
he cecum. The physiological considerations
a conservative surgical technic were:
ntion of a max. absorptive surface and retention
he ileocolic sphincter when possible for
ongation of time of intestinal content in
m and for one-way valvular action preventing
rgitation of materials into the ileum from
large intestine. The anatomical considera-
s were physiological also and concerned the
rruption of the extensive vascular bed dur-
extirpation of large segments in the ileo-
l region. Technic also chiefly concerned
ervation of vascularization. Success was
eved in 39 cases.

INFLUENCE OF JAUNDICE ON THE SMALL INTESTINAL MUCOSA.

(Ger.) Ihász, M.
Budapest, Hungary), J. Füsy, T. Jakab and
éfi. *Zbl. Chir*. 92(8):269-273, 1967.

dogs (12-15 kg), fasted for 24 hr. were
rotomized, and an intestinal loop 20 cm-long
ved from the region of the duodenojejunal
ure; the loop was mobilized with its blood
ly intact so that the mucosa could be
rved under a binocular dissecting scope at a
ification of 32. To be certain of the
ct of jaundice upon the intestinal mucosa,
ficial jaundice was produced by bile duct
tion. In other dogs an ileostomy was con-
cted from a blind loop about 20 cm proximal
he ileocecal junction so that the mucosa,
red with a transparent plastic cap and
red in place, could be examined under the
ecting microscope over a period of 10-14
. Contininuity of the intestine was re-
ed by end-to-end anastomosis. The degree of
dice was determined by serum bilirubin levels.
ore dogs with ileostomies, sodium taurocholate,
ocholate, or dehydrocholate was inj. The
rubin serum level was 0.26-0.40 mg% prior
peration in 7 dogs with subsequent bile duct
ligation; after 2 days the serum bilirubin level rose to 1.2 mg%; daily examination of the mucosa revealed no motility of the villi during the first 2 days, not even after mechanical irritation; the mucosa was edematous and hyperemic. Villi movement began on the third day and during hunger showed 60-150 contractions/min. as the edema and hyperemia decreased; rate of contraction increased upon mechanical irritation; at this stage the av. serum bilirubin conc. was 2 mg%; on the fifth day motility of the villi ceased as the bilirubin conc. reached 4.5 mg%, edema of the mucosa disappeared, motility of the villi did not return; serum bilirubin levels continued to rise until death of the animal within 2 wk. of bile duct ligation. The bile salts were inj to see if these compounds were the cause of the effects observed. The taurocholate, glycocholate and deoxycholate all showed the same effects (at different conc.). Inj. of 2 ml of 0.1% glycocholate caused sudden activity of the villi lasting about 1 min. then ceasing after the second min; the muscle of the villi relaxed; capillaries dilated and intestinal peristalsis decreased. These effects could be elicited from a conc. of glycocholate of 0.001%; taurocholate conc. were 0.05-0.01%; dehydrocholate required a conc. of 1% to be effective. Gallbladder bile produced the same results. The dog does not synthesize glycocholate.

9143 DUODENO-JEJUNITIS AND SIDEREMIA. PRELIMINARY STUDY.

(Fr.) Debray, C. (Bichat Inst., Paris), D. Cattan and C. Marche. *Nouv. Rev. Franc. Hemat*. 7(2):301-309, 1967.

Patients (23) with duodenojejunitis of various etiologies, were grouped as follows: Total atrophy of the villi in 8 cases; 3, of which had intolerance to gluten; 5, undetermined causes; subtotal atrophy of the villi in 2 cases, 1 with lack of γ-A-globulin in both serum and saliva, 1 of undeterminate cause; a tendency to villous atrophy, 9 cases, decreased height of villi; atrophy spots; 1 with deficient γ-globulins, 1, visceral neuropathic diabetes, 1, infectious duodenojejunitis, 1 with *Giardia lamblia* and/or staphlococci, 6 cases 2 of whom were gastrectomized; inflammatory duodenojejunitis, 4 cases without atrophy of the villi, 3 with *G.lamblia* and 1 probable infectious duodenojejunitis. Biopsies were obtained in multiple (5-12/subject) from the duodenum and upper loop of the jejunum; all were prepared for microscopy and stained; some semiquantitative determinations of staphylococci were made. Biopsies of bone and marrow were made in some instances of suspected osteomalacia. Levels of sideremia were measured; those with sideremia less than 60 μg were verified twice. The degree of steatorrhea was the av. amount of fat obtained in the 24-hr. stool collection on a minimum of 70 g of fat for 3 consecutive days. Among 10 subjects with steatorrhea 7 had a serum Fe level less than 60 μg. Among 12 subjects with hyposideremia 7 had steatorrhea. Among 10 hyposideremic patients who underwent a test for possible hyperglycemia (oral provocation), half showed a positive result. Among the 12 subjects with hyposideremia 6 had a hypoalbuminemia (less than 4 g%); 6 subjects with normal serum albumin had hyposideremia; 1 case with normal serum albumin and hyposideremia had exaggerated intestinal loss of protein. Among 14 cases of hypocalciuria 11 were hyposideremic. In general, hemoglobin conc. tended to be 75% or less among those with hyposideremia; the number of RBC was less than 4 million/mm^3; 6 had normal RBC count; 2 had a high count. Most cases of anemia were normochromic. In 1 case anemia was of 15-yr. duration, treated but with only incomplete and short-term results.

9144 ROLE OF VASCULAR INSUFFICIENCY IN DRUG-INDUCED SMALL BOWEL ULCERATION. (E.)

Mansfield, J. B. (Northwestern U. Med. Sch., Chicago, Ill.), F. B. Schoenfeld, M. Suwa, R. E. Geurkink and M. C. Anderson. Amer. J. Surg. 113(5):608-614, 1967.

In 24 dogs, two 0.5 g enteric-coated tablets were introduced into the distal ileum through a small opening made in the antimesenteric aspect of the intestine. Tablets (with a hole in the center) were tied to a fine silk ligature, anchored to intestinal wall near the ileostomy, and tablets were able to dissolve approx. 20 cm proximal to the ileocecal valve. In Group 1 (12) the tablets were NaCl; in Group 2, KCl. In 56, pressure in the splanchnic arterial circulation was reduced. Celiac and superior mesenteric arteries were exposed at their aortic origin, and pressures were obtained from the main trunk with a 25-gauge needle. Aortic pressure was monitored through a cannula in the right femoral artery. Pressure gradients were established between the aorta and the celiac and superior mesenteric arteries by constriction of the root of each vessel with a 1-0 silk ligature. Gradients of 25, 50 or 75% were produced between superior mesenteric artery and aorta; celiac pressure was reduced by 25% in all. Preliminary observations showed that a reduction in celiac artery aided in maintenance of an effective gradient in the ischemic superior mesenteric bed by a temporary reduction of collateral inflow. In 28 of those with reduced splanchnic artery pressure, NaCL tablets were introduced (Group 3); in 28, KCl (Group 4). Dogs that survived 48-72 hr. were sacrificed and the gastrointestinal tracts of all were carefully examined from the esophagus to the colon. Lesions were removed for histological study. Ten of 12 in Group 1 survived with no gross or microscopic abnormalities in any part of the gastrointestinal tract. Mortality in Group 2 was also 2 of 12, but gross and microscopic changes were observed: focal ulceration (1); diffuse inflammation in distal ileum (4). In Group 3 there was acute ileitis (4); ileal ulcer (1); hemorrhagic gastritis (4); superficial ulceration of duodenal lymphoid follicle (1). In Group 4 the number of lesions was increased compared with Group 3. Of 28, 15 had acute ileitis; 3, focal ulceration; 1, diffuse necrosis of mucos in the terminal ileum; 7, acute gastritis; 2, active ulcers; 1, focal gastric infarction. O 80, 54 had circumscribed areas of mucosal depression which were lymphoid follicles: duodenum (41); jejunum (12); ileum (1). The results are considered to support the theory t chronic vascular insufficiency predisposes the small intestine to injury by KCl.

9145 MALFORMATION OF THE SUPERIOR HORIZONT BRANCH OF THE DUODENUM. (Rus.)

Pyl'tsov, I. M. (Polyclin. No. 2, Moscow) and O. V. Turbina. Klin. Med. (Moskva) 45(4):99-1 1967.

Radiological examination revealed an anomaly i the development of the upper horizontal branch of the duodenum in 45 persons (15 males, 30 females; 38-56 yr. old). Changes included duodenal elongation slackening of various form loop formation, and lumen dilatation (1.5-2.0 fold) in 20 patients; this segment had significant motility. The position of the upper horizontal branch corresponded to variant I in 20 cases, to variant II in 7, to variant III i 18, to variant IV in 8 and to variant V in 2. No other anomalies were present. Advance of t contrast mass was delayed at the duodenum mobi partialis (the developmental anomaly, so-named duodenostasis of variable degree with retentio of Ba suspension from 1-3 hr. after initiation of the study was noted in all patients. Complaints were found in 40 of 45 cases; dull pai in the epigastric region occurred in 22, acute seizures of pain in 10, regurgitation or nause in 14, and jaundice in 3. Such symptoms were found for several yr., and were diagnosed as gastritis in 20, peptic ulcer in 15 and cholec titis in 5. Typical clinical symptoms in this form of anomaly of the duodenum were not obser Duodenum mobile partialis does not exclude the presence of accompanying diseases, such as gastritis, peptic ulcer and cholecystitis; in these cases, the intestinal anomaly contribute to more frequent recurrences of the accompanyi disease.

9146 INTESTINE VIABILITY OF MESENTERIC VESSELS. (Rus.)

Artemkina, N. I. ar V. V. Nekachalov. Eksp. Khir. Anest. 11(6): 19-21, 1966.

Both early (up to 7 hr. after initiation of th experiment) and late (at 10-12 hr.) changes i intestinal structure were found in rabbits (2 with experimentally-induced thrombosis. Early changes were manifested by vascular disorders (in the form of hemorrhagic infarction or mark anemia) and were reversible. Late changes developed at 10-12 hr. of the experiment, at which time the first symptoms of peritonitis and bacterial colonies in the intestinal wall were observed. Admin. of heparin (i.v.) duri a state of progressive intestinal gangrene whi

conditioned by obstruction of the mesenteric
sels, had no effect on the development of the
ease. Experimental results of treatment were
follows: 1) from 0-3 hr. after induction of
ombosis and admin. of heparin, 5 survivors and
ead; 2) from 3-6 hr. after the same procedure,
urvivors and 3 dead; and 3) from 6 hr. onward
er the same procedure there were 1 survivor
3 dead. Of those rabbits untreated, 1 sur-
ed and 8 died. Effective treatment of thrombo-
olic intestinal lesions is dependent upon
ly diagnosis and early operative intervention.

7 DUODENOPANCREATIC HOMOGRAFTS IN THE DOG.
(Fr.) Cuilleret, J. (Hotel Dieu, Lyon,
nce), C. Vieville, X. Delore, Y. Auffray,
Chavent, M. Barteille, J. Falconnet, J. Gilly,
Guillemin and J. Descotes. J. Chir. (Paris)
2):177-190, 1967.

lowing duodenopancreatic autotransplantation
th pancreaticoduodenal anastomosis of the
od vessels to the splenic vessels), the
tality rate in 10 dogs was 100%; 1 animal died
er 3 hr. of a reanimation failure, and the
er 9 dogs died after 12 hr.-3 days of venous
or peripheral arterial thrombosis (1),
orrhage (1), acute gastric dilatation (1),
denal necrosis (1) or Carré's disease (1).
od sugar levels rose during the intervention,
fell rapidly in the next 12 hr. to hypo-
cemic levels; amylase levels were not
nificantly increased, and external pancreatic
retion was always abundant several min. after
blood vessel clamps were released. None of
autografts developed acute pancreatitis.
lowing pancreatic homotransplantation, 14 of
dogs died within 48 hr.; 9 of these dogs had
ergone a 1-stage procedure and 5, a 2-stage
cedure. Causes of early postoperative death
e hemorrhage from the aortic stump (6), acute
rinolysis (1), peripheral arterial (2) or
ous thrombosis (2), intestinal volvulus (1),
itonitis (1) or intestinal invagination
ondary to pancreatectomy, reduced during the
fting procedure (1). In the other 10 dogs
survival time was 4-7 days in 7 and 12-16
s in 3; the cause of death was related only
graft rejection in 4 animals (sacrificed
er 7-16 days). The postoperative condition
good in animals surviving more than 48 hr.
erglycemia developed immediately after pan-
atectomy in all animals, but was rapidly
trolled by infusion of serum containing
tonic levels of glucose; in the animals sur-
ing more than 48 hr. the serum glucose levels
e normal, although an episode of secondary
erial thrombosis in 1 animal was accompanied
hyperglycemia, as were the terminal complica-
ns in all animals. A prolonged increase in
um amylase levels was also noted, but no
nges in SGOT or SGPT levels were noted in
eral dogs surviving 4 days or more. None of
se tests proved specific for graft rejection.
tological changes in the homografts of dogs
viving more than 4 days included interlobular edema with lymphoplasmacytic infiltration, followed (in 2 dogs) by arterial lesions; the terminal stage of rejection was accompanied by edema and necrosis of the exocrine tissue, sparing the islets of Langerhans for a prolonged period. Only 1 animal showed signs of acute pancreatitis.

9148 A SIMPLE DEVICE FOR TIMED SAMPLING IN PHYSIOLOGICAL STUDIES OF THE HUMAN SMALL BOWEL IN VIVO. (E.) Barreiro, M. A. (McGill U. Med. Clin., Montreal, Canada), R. D. McKenna and I. T. Beck. Gastroint. Endosc. 13(4):28-30, 1967.

Normal humans (41) underwent a total of 45 intubations of the small intestine. In 19 the proximal 50 cm of jejunum was studied through a multiple-lumen polyvinyl tube; internal diameter of catheter was 1.12 mm. A "basket" of polyvinyl tubing surrounded the main collecting catheter. Several 4-cm segments of 00 surgical wire were threaded through the polyvinyl tubing. The ends of the tubing were flame-sealed, flattened by gentle pressure with surgical forceps, and glued on to the main tube with tetrahydrofurane. The wire was completely enveloped in polyvinyl tubing and could not damage the intestinal wall. Of 45 intubations, 23 were unsuccessful (51.1%). Of these, 12 (52.1%) were due to sampling difficulties, but after introduction of the basket, there was only 1 failure in 26 attempts (3.8%). The proximal segment of jejunum was studied by 22 intubations in 19 patients. In 64 different experiments, there were 845 intraluminal samplings in 1644 min. of sampling time. The av. time between samples was less than 2 min. and sample vol. were 3-5 ml.

9149 INTESTINAL ANGINA SECONDARY TO COMPRESSION OF THE COELIAC AXIS. (E.) Terpstra, J. L. (Leiden U. Hosp., Netherlands). Arch. Chir. Neerl. 18(4):245-253, 1966.

Surgical treatment of hiatus aorticus involves midline incision in the upper abdomen; opening of the lesser omental bursa with stomach and pancreas being kept in a caudal position; the celiac artery is approached ventrocranially and dissected free; whenever possible the celiac nerve plexus is left intact; a curved clamp is pushed below the middle part of the rim of the hiatus anterior to the aorta and, with this as a guide, the hiatus is divided and cut to a depth of 3-4 cm; small arterial branches to the diaphragm from the main stem of the celiac artery are ligated to prevent problem bleeding, while bleeding from small arterial branches in the hiatus can be stopped by coagulation. The lateral and caudal sides of the celiac artery are not touched, overlying structures are not ligated, and the abdominal wall is sutured in layers. Seven patients were operated on: 4 became asymptomatic, in 1 symptoms were alleviated, but wasting continued, and 2 received no benefit. In the latter 3 there was a distinct compression of the celiac artery with a pressure of more than 25 cm Hg between aorta and celiac artery. The lack of improvement was not surprising since the indication for operation was nonspecific abdominal pain present for several yr. with no pathological finding other than narrowing of the celiac artery on X-ray examination. On the basis of symptoms, anatomical and embryological aspects, it is suggested that the syndrome of intestinal angina is a new clinical entity. A longer follow-up is suggested (max. to date, 18 mo.) before definite conclusions can be reached.

97 STUDIES ON OLIGOSACCHARIDE SULFATES AND MONOSACCHARIDE SULFATES FOR MEDICAL
RPOSES. I. ANTIPEPTIC AND ANTIULCEROGENIC
OPERTIES OF THE DISACCHARIDE SULFATES. (Jap.)
mekata, M. (Chugai Pharm. Co., Ltd., Tokyo),
Matsuo, A. Momose and M. Takagi. Yakugaku
sshi (J. Pharm. Soc. Jap.) 87(4):376-380, 1967.

e relatively low molecular wt. compounds, salts of sucrose, lactose and maltose lfates, showed strong antipepsin (in vitro) d antiulcer (pylorus-ligated rats) activities mparable to the sulfate esters of polysaccharides en highly sulfated. These effects were ineased with increasing number of sulfate dicals. The nonreducing sucrose salts having primary hydroxyls in its molecule had the rongest activity, although the comparable mpounds of lactose and maltose were not much ss active. Thus when sucrose sulfate (21.2% lfur) was added to standardized pepsin soln. in ounts of 1, 3, 5 and 7 mg/ml, the pepsin tivities remaining were 80.3, 54.0 36.7 and .2%, resp., of the activity of preparations thout sucrose sulfate. Comparing the enzyme tivity remaining after the addition of 5 mg of number of different substances to separate ml vol. of pepsin soln., the following perntages were obtained: heparin (58.4), ondroitin sulfate (75.2), dextran sulfate 7.6), oxidized starch sulfate (32.9). Doses 25, 50, and 75 mg sucrose sulfate (21.2% lfur) inj. i.v. into groups of 5 Shay rats each ve complete protection against ulcer formation, did 30 mg of oxidized starch sulfate (14.6% lfur); all control animals developed multiple cers. Gastric juice vol. was normal, but free d total acid were depressed to a greater tent by the sucrose compound (as much as 33%) an by oxidized starch sulfate (11%); pepsin nc. was reduced to 40% by the sucrose compound compared to a reduction to 29% by the idized starch sulfate. The same experiment peated with the sucrose sulfate (21.2% sulfur) j. s.c. showed no effect whatever upon the cidence of peptic ulcer or upon the composition gastric juice. These experimental results ggest that the sulfate radical bonded to the imary hydroxyl is the active group.

198 CONSTITUTIONAL FACTORS AND THE FREQUENCY OF IMMOBILIZATION ULCER IN THE RAT.
Fr.) Lambert, R. (Fac. Med., Lyon, France),
. S. Martin, G. Vouillon and F. Martin. C.R.
oc. Biol. (Paris) 160(11):2127-2131, 1966.

total of 690 Wistar rats, 314 males and 376 emales (100-400 g), from 7 different regions of rance were immobilized in a metal grill corset or 24 hr.; they were not fasted and received 10 l of physiological saline i.p. The control nimals, in like number, were untreated. Ulcers eveloped in 429 (62%) of the restrained rats, a omewhat lower percentage than reported by others. he number of ulcerated male rats was 117 (56%), the number of ulcerated females, 252 (67%). Of the 195 rats weighing 100-150 g, 168 (86%) developed ulcers, as did 190 of 323 (59%) weighing 150-200 g, and 71 of 172 (41%) weighing more than 200 g. Thus the young were the most susceptible. The geographic origin exerted an effect upon the frequency of ulceration, varying from 43-81%, but independent of the distance transported. The effect of stress due to transportation was ruled out by testing animals 1-22 days after their delivery to the laboratory. The differences seem to result from their previous environment. The influence of the time of yr. with respect to temperature and duration of daylight was tested: 94 of 158 rats tested (59%) formed ulcers during February and March; 209 of 266 (78%) tested during April and May and 114 of 244 rats (46%) tested in June and July developed ulcers. Grouped according to geographic origin with respect to high and low susceptibility to restraint ulceration and also in terms of time of yr. (three 2-mo. periods as above) the percentages were for the high-incidence group 72, 86 and 62, resp., and for the low-incidence group 48, 64, and 39, resp., indicating the operation of independently variable factors.

9199 THE EFFECT OF 1,3-DIHYDRO-7-NITRO-5-PHENYL-2H-1,4 BENZODIAZEPINE (MOGADON) ON GASTRIC ULCERS PRODUCED BY RESTRAINING RATS AND ALBINO MICE. (Fr.) Mercier, J. (Lab. Human Biol., Marseille, France) and S. Lumbroso. Arch. Int. Pharmacodyn. 167(1):35-38, 1967.

Admin. s.c. of 10-20 mg/kg of the title benzodiazepine derivative to rats which were to be restrained for 7 hr. reduced the production of gastric ulcers in 20, 40 and 40% of the cases, resp. Max. protection was obtained at 15 mg/kg. A more significant protection was obtained when admin. to albino mice: 5, 15 and 20 mg/kg s.c. provided protection in 20, 40 and 70% of the cases, resp. In part, this increased sensitivity found in mice resulted from their having been fasted for 24 hr. prior to confinement. Restraining alone produced at least 1 gastric ulcer in 60% of the rats and 70% of the mice. The data indicate that the agent is 3 times as active as a comparable dose of Librium in protecting these animals from developing restraint gastric ulcers, despite the fact that it is approx. 10 times more active than chlordiazepoxide as a tranquilizing agent.

9200 EXPERIMENTAL GASTRIC ULCER BY SEROTONIN IN THE RAT AND ITS PREVENTION. (Fr.) Bel, A. (Red Cross Hosp., Lyon, France), R. Levrat, J. Nesmoz and M. Girard. Rev. Int. Hepat. 17(2):65-78, 1967.

In 35 rats inj. s.c. with 15 mg/kg serotonin 20 and 6 hr. before sacrifice, no deaths occurred; vasomotor reactions in spots and bands, sometimes diffuse or deep red or purple, on which ulcerations erupted, appeared in 54%; ulcers occurred in different numbers up to 20/rat usually located near the greater curvature, irregular in shape, covered with a dark crust, surrounded by a halo of vasodilatation when not situated in a spot or band of vasodilatation. These ulcers of hemorrhagic origin occurred in 88.5% of the animals; the ulcer index (number of ulcers/rat) was 9. Normal and vagotomized animals showed no difference upon inj. of serotonin. Nephrectomy had no decided effect upon the action of serotonin whereas adrenalectomy strongly potentiated the effect of serotonin; after adrenalectomy, the standard doses of serotonin produced ulcers in 92.3% with an ulcer index of 22.1. Normal rats were inj. (route not given) with a number of protective compounds 0.5 hr. before inj. of serotonin. These compounds, the dosages, and the resulting ulcer indices were: (1) methysergide, 2 mg/kg, index 1.7; 4 mg/kg, index 6; 8 mg/kg, index 4.5; (2) cyproheptadine, 1 mg/kg, index 1.3; 2 mg/kg, index 2.0; (3) dimethothiazine, 10 mg/kg, index 12; 15 ml/kg, index 7.5; 40 mg/kg, index 7; 100 mg/kg, index 4; (4) chlorphenoxamine, 20 mg/kg, index 9; 30 mg/kg, index 2; 40 mg/kg, index 4; (5) trioxypropiophenone, 30 mg/kg, index 9; (6) L.D 3055, 2 mg/kg, index 11.6; 4 mg/kg, index 9. Urogastrone (3-12 U) was ineffective.

9201 PROTECTION EFFECT OF α,α-DIPHENYL-α-PROPARGOXYACETIC ACID β-DIMETHYLAMINOETHYL ESTER HYDROCHLORIDE ON SHAY ULCER. (It.) Torrielli, M. V. (U. Perugia, Italy) and P. Capitanucci. Boll. Soc. Ital. Biol. Sper. 42(24):1996-2001, 1966.

Several groups of male Wistar rats, weighing approx. 180 g at the start of the experiment, were subjected to Shay ligature of the pylorus 17 hr. before sacrifice. The experimental drug was admin. 0.5 hr. prior to surgery, in single, s.c. doses which progressed geometrically by a factor of 2 from 1.875-30.0 mg/kg. The degree of ulceration induced and the amount of gastric damage involved were tabulated in terms of Placer's Index for control animals and for animals receiving 3.75, 7.5, 15.0 and 30.0 mg/kg, as follows: 94.7, 56.3, 47.9, 57.8 and 63.8, resp.; indicating a max. protective effect at a dose level of 7.5 mg/kg, with progressive diminution of protective activity thereafter. Mean measurements of the total vol. of gastric secretion, pH and both total and free acid at dose levels 1.875-15.0 mg/kg were essentially consonant with the indicated reversal of the drug effect.

9202 PREVENTIVE ACTION OF ISOPROPAMIDE ON EXPERIMENTAL STRESS ULCER OF WHITE RATS. (Fr.) Liefooghe, J. (Fac. Med., Lille, France) and Y. Vantorre. J. Sci. Med. Lille 85(3): 169-174, 1967.

Three groups of rats were maintained under stress conditions, the animals being placed in a wire-latticed corset, with 4 holes for the paws, so that they do not touch the ground. Al rats in the first group were raised in the laboratory; the control group showed 31% gastri ulcers, while those inj. twice prior to the tes with Isopropamide showed a 12% incidence. In the second group the rats were brought in from outside, and the corresponding incidence of ulcers was 60% and 53%. In the third group the rats were also brought in from outside, but the Isopropamide was perfused s.c. continuously for the entire period of stress, which was also preceded by an inj. of Isopropamide (4 mg/kg/da In the control group, 80% had ulcers, while 14.3% of the treated animals had ulcers. The difference is highly significant and it is concluded that isopropamide in certain experimenta conditions efficiently prevents gastric lesions (gastric congestion, ulcerations) due to stress principally by acting as an anticholinergic.

9203 EXPERIMENTAL PRODUCTION OF CHRONIC PEPTIC ULCER. (Sp.) Gutiérrez Rivas, V. E., G. Guardia Salas, G. López De Aguilar an A. Olivera N. Acad. Peru. Cirug. 19(1):33-39, 1966.

Peptic ulcers were induced experimentally in 15 dogs (9-15 kg body wt.) according to the Mann-Williamson Type 1 method in which end-to-end anastomosis was performed between the stomach and distal end of the jejunum and end-to-side anastomosis between the proximal end of the jejunum and terminal portion of the ileum. Dextrose soln. and tetracycline were admin. during surgery to all but 5 dogs. These animals died several days later from rupture at the sit of anastomosis and peritonitis (4 dogs) or obstruction at the level of the gastrojejunal anastomosis (1). By day 15, the surviving animals had lost 40% of their body wt.; by day 21, animals had lost 70% of their body wt. and the cachexia had become worse. The Thévenon feces test was positive in all animals; all had hypochromic anemia and hypoproteinemia; none showed signs of hepatic insufficiency. By days 21 and 27, radiologic signs of peptic ulcer were observed. The presence of peptic ulcer wa confirmed at autopsy. Death occurred between days 26 and 38; causes of death were perforatio of peptic ulcer (2), bleeding at the site of gastrojejunal anastomosis (2), marked malnutrit (3), or bronchopneumonia (3). The etiological cause of peptic ulcer in each case is not entirely clear: a principal factor seems to be the constant trauma caused by jets of hydrochloric acid and pepsin against a mucous membrane not protected by alkaline secretions as i the case normally in the upper portions of the intestine, although marked hypoproteinemia may also be an important factor in ulcer production

9204 RESULTS OF SURGERY FOR PEPTIC ULCER OF THE STOMACH AND DUODENUM. EXPERIENCE WITH THREE THOUSAND, THREE HUNDRED GASTRIC OPERATIONS. (E.) Chrysospathis, P. (U. Athens

ece) and B. Golematis. Pacif. Med. Surg.
2):96-104, 1967.

ee diagnostic tools were used: X-ray, measure-
t of gastric acidity, Gastrocamera. Operative
cedures in authors' clinic were gastroenteros-
y (3.21%), vagotomy and drainage (4.7%),
tial gastrectomy (92%), total gastrectomy
1%). Patients were 82% men, 18% women. The
distribution was: up to 30 yr., 19%; 30-60,
; above 60, 10%. Ulcer locations were: stomach
.3%), duodenum (75.1%), both (0.9%), pyloric
nosis (9.8%), stomal ulcer (1.9%). Gastro-
erostomy was done in the aged with pyloric
nosis, poor physical condition and severe
er symptoms, or perforation of duodenal ulcer.
106, cases, satisfactory results were obtained
100, recurrent ulcer in 1, mortality of 5.
otomy was performed in hyposecretors under 30
, active pulmonary tuberculosis, pyscho-
rosis with intractable ulcer symptoms, poor
ks, those with technical problems of duodenal
mp closure aged persons with active ulcer and
plications. Of 155 cases, favorable results
e obtained in 136. Both types of gastrectomy
e used. Billroth-I was done in those with
tric and duodenal ulcers, with 50% and 67%
mach resection, resp., and was preferred
ause of its more physiological nature. Of
of these procedures, 246 showed the following
plications over 4-6 yr.: recurrent ulcer,
mia, stomal dysfunction, dumping syndrome,
tprandial epigastric discomfort. Billroth-II
done in 2618 cases in 3 variations: Reichel-
ya (1231), since discarded because of high
quency of complications and mortality (1.6%);
fmeister-Finsterer (948) with 0.42% mortality;
ificial pyloric canal type, with few complica-
ns and zero mortality. The latter is favored,
purpose to delay gastric emptying and to
ulate passing of stomach contents by a valvular
hanism added in the upper end of canal with
errupted fine silk sutures. Its advantage is
gain (in 60%), ability to enjoy a free diet,
a low incidence of stomach intolerance to
k. In a 6-yr. follow-up of 120 cases, com-
ints were anemia (1), superficial gastritis
, diarrhea (1) (total 2.5%). In the first 2
lroth-II technics, there were 9% and 7.3%
plaints, resp.

5 GASTRIC SECRETORY TESTS. PRO AND CON.
(E.) Passaro, E., Jr. (Wadsworth Hosp.,
Angeles, Calif.) and H. E. Gordon. Amer. J.
g. 114(2):333-339, 1967.

otal of 1134 gastric secretory tests were
ducted over a 4-yr. period on a variety of
ients. A betazole secretory test was per-
med on 665 patients as follows: in 285 before
ration and 105 after operation for peptic
er, in 170 patients with miscellaneous
gnoses and in 105 normal subjects (patients
iting herniorrhaphy who gave no indication of
tic ulcers or other serious illness), who
ved as controls. A Hollander (insulin) test
was done on 359 patients as follows: in 144 before operation and 198 after operation for peptic ulcer and in 47 patients with miscellaneous diagnoses. In addition, gastric secretory tests (unspecified) were performed on 22 patients with chronic pancreatitis and 4 patients with parathyroid adenomas. Only 20% of the patients with duodenal ulcer had a peak rate of secretion beyond the range of controls, with the betazole test. When comparison was made between these patients and controls in each decade of life; however, a statistically significant difference emerged; older patients with duodenal ulcer had a level of gastric secretion which was significantly higher than their peers in the control group. In patients with gastric ulcer, results were more variable; although the av. level of secretion in this group was lower than that in the control group or the group of patients with duodenal ulcer, the difference was not statistically significant. A postoperative Hollander test, used to determine vagal integrity after operation, delineated 3 groups of patients: 1) those in whom no increase in gastrin secretion occurred after insulin hypoglycemia; these were judged to have a complete vagotomy; 2) those in whom an increase over basal levels occurred in the first hr., which indicated an incomplete vagotomy; and 3) those in whom a modest increase in acid secretion over basal levels occurred during the second or third hr. after stimulation; the significance of this latter response was not clear, but it was considered to be indicative of incomplete vagotomy. In spite of histologic evidence of both vagal trunks having been excised in 22 patients, 32 (16%) of 198 patients had an incomplete vagotomy by these Hollander criteria; in the remaining 10 the left nerve was missed twice and neither nerve was excised in 8. The secretory response in 22 patients with histologic evidence of chronic pancreatitis was not significantly different from that of the control group; no patient had hypersecretion. The level of gastric secretion in 4 patients with parathyroid adenomas was well within the normal range; however, there was a decrease in gastric secretion after removal of a parathyroid adenoma in a patient with multiple endocrine adenopathies. While the standard betazole test is safe, practical, gives highly reproducible results and is easy to perform, the results of this study (and others) show that the test has only limited application to the diagnosis of peptic ulcer. Achlorhydria is best determined by a standard betazole test. The Hollander test is not recommended for patients with a history of severe heart disease, strokes, seizures or general debilitation.

9206 MAXIMAL HISTAMINE RESPONSE IN DUODENAL ULCER PATIENTS. (E.) Patel, J. M. (Med. Coll., Baroda, India), B. K. Vyas, W. P. Small and P. M. Trivedi. Indian J. Surg. 29(2): 57-65, 1967.

Of 94 duodenal ulcer patients, 91 were vegetarians.

There were 40 normal controls, (half each sex) from the hospital's surgical wards. The method of Kay was used; 50-100 mg promethazine was used as an antihistamine. On monitoring, the Levin tube had to be readjusted in 56% of the cases. Eight women were dropped because of tube discomfort. Histamine was well tolerated by all; 11% showed a mild histamine reaction. The test was repeated after 1-4 days in 6 cases of duodenal ulcer; basal secretion in the 2 tests varied widely (6-18%); max. acid output was fairly comparable (3.1-8.2%); the av. difference between the 2 tests was 5.7%. Av. basal secretion and normal max. acid output in men and women, resp., were: 2.5 and 2.0 mEq; 12.02 and 7.19 mEq. There was no significant difference in acid secretion between uncomplicated male cases (48) and controls; acid secretion was significantly lower in uncomplicated women cases than in uncomplicated men. Basal output increased with age to 40 yr. and then decreased. Max. acid output in both sexes was linear with age, with a peak at 31-40 yr. The parabolic curve of wt. in both sexes correlated well with the parabolic curve of max. output up to 50 yr. There were significant differences in max. acid output between men and women; in each age group, females secreted a lesser amount of basal and max. acid than corresponding males; at all age groups, the av. hemoglobin levels for females were lower than males. Both acid outputs in both sexes increased with wt.; women secreted less acid than men, except in the wt. group of 31-40 kg at 31-40 yr. and 41-50 kg at 41-50 yr. Acid output in smokers was higher than in nonsmokers. With increase in duration of symptoms up to 13 yr., there was a gradual rise in max. acid output, which later declined. There was no significant difference between uncomplicated cases and those with hemorrhage (10) or perforation (13); there was a significant difference in those with stenosis (20).

9207 POSTMORTEM STUDIES ON THE RELATIONSHIP BETWEEN SEVERE ARTERIOSCLEROSIS AND GASTRODUODENAL DISORDERS. (Ger.) Lange, H.-J. (Johannes-Gutenberg U., Mainz, Germany) and K.-J. Hempel. Bruns Beitr. Klin. Chir. 214(2):202-212, 1967.

In 2774 autopsy reports on 1646 male and 1128 female cadavers of persons more than 40 yr. old, the degree of arteriosclerosis was noted as was the extent and severity of gastric and duodenal ulcer; correlations were made not only with respect to these diseases (arteriosclerosis and ulcer) but these were correlated with cancer and also with accidental death. Every possible comparison was made. The data were treated statistically. It was concluded that, avoiding heterogeneity and errors by unequal selection in the comparative groups, in males severe general arteriosclerosis was found considerably more frequently in cases with ulcers (without accident) when compared to a group of males who were killed in an accident (with and without ulcer). The difference is statistically significant.

9208 ISOENZYMES OF ALKALINE PHOSPHATASE IN PATIENTS OPERATED UPON FOR PEPTIC ULC (E.) Pulvertaft, C. N. (York City Gen. Hosp., York, England), J. E. Luffman, E. B. Robson, H Harris and M. J. S. Langman. Lancet 1(7484): 237-239, 1967.

Studies were made on 5 55 men who had undergon Polya gastrectomy to determine if increased levels of total serum alkaline phosphatase resulted from an increase in the intestinal component. The mean serum alkaline phosphatas was greater in individuals with Blood-Groups 0 and B (8.2 King-Armstrong U) than in Group-A individuals (7.2 U) but the difference was not statistically significant. The intestinal alkaline phosphatase component was studied by electrophoresis in 134 men treated by Polya partial gastrectomy and in 69 controls treated by vagotomy or drainage. As in normal persons the intestinal fraction was seldom found in nc secretors or in Group-A secretors, whatever th gastric operation done. It was found, as expected, in the serum of 0 and B secretors, but no significant differences were detected between the frequencies of incidence in Polya gastrectomy patients and in those who underwen vagotomy and drainage. No suggestion was foun that the intestinal isoenzyme appeared especia often after surgery in those patients with preoperative total phosphatase levels of 12 or more King-Armstrong U. The increased total serum alkaline phosphatase levels seen in partially gastrectomized patients is probably not due to increased amounts of the intestinal component.

9209 THE CONTENT OF CERTAIN PROTEIN-BOUND SUGARS IN GASTRIC JUICE OF PATIENTS GASTRODUODENAL ULCER. (Rus.) Rabinovich, P. (Chita Med. Inst., USSR). Ter. Arkh. 39(1): 43-49, 1967.

A study was performed on 144 patients (103 men 41 women) with peptic ulcer (pyloro-duodenal 96, and on the lesser curvature in the subcardiac region in 48) of 1-30 yr. duration, 2 patients (14 men, 15 women) with chronic cholecystitis or gastritis, gastric carcinoma and dysentery, and in 29 healthy normals (18 men, 11 women) who were 17-65 yr. old. Durin exacerbation of duodenal peptic ulcer, the co of all protein-bound carbohydrates in the gastric juice, especially after fasting, was decreased. During exacerbation of gastric peptic ulcer the conc. of fucose and sialic a in the gastric juice (fasting) was decreased, and the conc. of hexoses was decreased only insignificantly. After stimulation of secret the differences in conc. of protein-bound carbohydrates in the various groups were insignificant. During the active period of tic ulcer the content of fucose bound to oluble mucin proteins in the gastric juice decreased. The conc. of fucose in gastric ce was markedly increased during the initial iod of recovery. The conc. of sialic acids protein-bound hexoses and hexosamines in- ased only at the pyloroduodenal localization the ulcers. Decrease in the amount of fucose the gastric juice glycoproteins, especially in oluble mucin, may play a decisive role in kening of the mucous membrane of the gastro- denal portion of the peptic ulcer and in the hanism of pain production.

0 PHARMACODYNAMIC STUDY OF THE ASSOCIATION OF AN ANTISPASMODIC AGENT AND TRAN- LLIZER RECOMMENDED IN THE TREATMENT OF DIGES- E TRACT ULCERS. (Fr.) Mercier, J. (Fac. Med. rm., Marseille, France), S. Dessaigne, M. R. end, P. Etzensperger and J. Veran. *Path. Biol.* *ris)* 15(7-8):441-446, 1967.

various pharmacodynamic properties of 170-JD iglium"), composed of a tranquillizer (mephen- lone; OM-518) and an antispasmodic agent octylatropine bromide; AD-122), were deter- ed experimentally. The acute toxicity of the ociation (LD_{50} = 2.25 g/kg) was determined in ss albino mice according to the Karber-Behrens hod; the compound was classified as "slightly ic" according to the Hodge-Sterner classifica- n. In small doses (5.1 and 10.2 mg/kg i.v.), -JD exerted an inhibitory effect upon gastric d secretion (determined by the Noordwijk- sen method) in Wistar albino rats. The speed intestinal transit was clearly diminished by -JD; the intestinal depressant effect of 122 was 2.4-4 times greater than equivalent es (10 and 20 mg/kg p.o.) of atropine. The ative and preventive *in vitro* effects of -JD on acetylcholine-induced duodenal spasm rats was 4 and 10 times, resp., less than t of atropine and 100 times (in both cases) ater than that of papaverine; AD-122 was ally effective as atropine, but 15 times less ective than papaverine in relieving $BaCl_2$- uced duodenal spasm. Spontaneous gastro- estinal contractions in chloralosed dogs were ested for 20 min. following i.v. inj. of 50 kg of 170-JD. Pilocarpine (1 mg/kg) and stigmine (30-50 μg/kg)-induced gastrointestinal tractions were inhibited by doses of 50 and μg/kg of 170-JD. The stimulating effect of phine hydrochloride (1 mg/kg) on the digestive ct was inhibited by 100 μg/kg of 170-JD, ereas 250 μg/kg of 170-JD failed to inhibit stimulating effect of $BaCl_2$ (1 mg/kg). -JD inhibited sphincter of Oddi contraction luced by morphine in chloralosed dogs, but en inj. before morphine caused only a reduction the degree of contraction. Like atropine, 122 decreased or temporarily suppressed pilo- rpine-induced salivation at doses of 20, 30, 50 μ g/kg, and caused prolonged inhibition doses of 100 μg/kg. 170-JD showed no chronic icity (except for decreased wt.) in albino rats and rabbits (Bourgogne "Fauve" strain) treated with human therapeutic doses (34 mg/kg/60-kg adult) and 5 and 10 times that amount for 78 (rats) or 101 days (rabbits). The sedative, mydriatic, respiratory, and cardiovascular effects of 170-JD were also tested.

9211 EVACUATORY GASTRIC FUNCTION IN DUODENAL ULCER PATIENTS EVALUATED BY MEANS OF RADIOCAPSULE WITH pH RECORDER. (Rus.) Votchal, B. E. (Cent. Inst. Advanced Train, Phys., Moscow), A. S. Belousov and G. L. Levin. *Klin. Med.* *(Moskva)* 45(3):20-26, 1967.

This study was made on 33 patients (25 men, 8 women; 18-45 yr. old) with duodenal ulcer of less than 1 to more than 5 yr. duration. In 18 persons the type of acid secretion was excitable; in 5 it was inhibitory, in 7, asthenic, and in 3 it was inert. In healthy persons with an excitable type of acid secretion, evacuatory function (in a fasting state) displayed a period of pH fluctuation which lasted 5-10 min. and alternated with periods of rest; there were stable pH values of 7.0-8.0 for up to 40 min. after feeding a bread breakfast, i.e., gastric evacuation was absent. Approx. 20-40 min. after a bread breakfast, there were rhythmical, undulatory fluctuations of pH lasting 1-2 min., with a sharp decrease of pH to 3.0-4.0 and a rapid return to initial values. The evacuatory function in patients with duodenal ulcer who had an excitable type of acid secretion showed a period of pH fluctuation lasting 30 min. or more; there was no period in which evacuation did not occur; i.e., after a bread breakfast, significant and irregular discharges of gastric content into the duodenum occurred; after a bread breakfast there were marked pH fluctuations, with duration of individual waves of up to 20 min. or more. In patients with duodenal ulcer, during the period of exacerbation (markedly pronounced pain syndrome, vomiting) there were periods of especially pronounced gastric evacuation. An analogous picture of gastric evacuation, studied by means of radiotelemetry, was found in patients with an asthenic and inert type of acid secretion; however, in a number of patients with an asthenic type of acid secretion, immediately after a bread breakfast there was a period of no gastric evacuation lasting 20-30 min., and at the same time duodenal pH was 7.0-8.0; this was followed by vigorous gastric evacuation and alteration of pH fluctuations, with individual large fluctuations lasting up to 30 min. In patients with duodenal ulcer and an inhibitory type of acid secretion, during a period of exacerbation feeding of a bread breakfast was followed by continuous discharge of gastric contents, with a gradual decrease in duodenal pH (to 1.0-2.0); this continuous discharge of gastric contents lasted for 1 or more hr. in several patients. This was followed by a period of undulating pH fluctuations. Thus, the radiocapsule with a pH recorder may be used for study of gastric evacuation in both healthy individuals and in those with duodenal ulcers. Three case histories are presented in some detail.

9212 MORPHOLOGICAL CHANGES OF THE DUODENAL MUCOUS MEMBRANE IN PEPTIC ULCER (ASPIRATION BIOPSY DATA). (Rus.) Sadkova, T. N. (Lab. Gastroent., Acad. Med. Sci., Leningrad, USSR) and V. M. Zolotova. *Klin. Med. (Moskva)* 45(2):35-40, 1967.

A study of aspiration biopsy data from 63 patients with peptic ulcers of gastric (15) and duodenal (48) location revealed 4 types of morphological changes of the duodenal mucous membrane. A normal mucous membrane was found in 10 of 15 with gastric ulcers and 12 of 48 with duodenal ulcers. A superficial duodenitis (characterized by a variable cellular height, subepithelial edema, frequent epithelial desquamation and removal of borders between the cells) was present in 1 of 15 with gastric ulcers and 2 of 48 with duodenal ulcers. A diffuse duodenitis (marked lymphocytic-plasmacytic infiltration often in combination with moderate eosinophilia, and infiltration of Brünner's glands from the submucous into the mucous layer) was observed in 2 of 15 and 6 of 48, resp. Atrophic duodenitis (characterized by villous atrophy, reduced thickness of the mucous membrane, crypts, and a larger amount of connective tissue) was moderately pronounced in 2 of 15 and 23 of 48, resp., and markedly pronounced in 5 of 48. Qualitative and quantitative alterations of the glandular epithelium were directly dependent upon the extent of the pathologic process in the mucous membrane. Three phases of the morphologic process were found in duodenitis, i.e., exacerbation, regression and remission. In peptic ulcer uncomplicated by duodenitis, pain was periodic (depending on the time of feeding, and quality and quantity of food), and disappeared after eating; exacerbation of pain was seasonal in character. Such variation(s) were present in 25 of 63 patients. Peptic ulcer complicated by chronic duodenitis and with a morphologic picture of a diffuse and atrophic process was diagnosed in 38 of 63. These patients had a persistent pain syndrome. Antiulcer therapy was effective in the former group, and only slightly effective in the latter group. The dumping syndrome was found in 5 of 38 patients. It is concluded that aspiration biopsy facilitates the determination of different forms of duodenitis in patients with peptic ulcer. One case history is given in detail.

9213 PHARMACOLOGIC AND CLINICO-PHARMACOLOGIC STUDIES ON NEW ULCER-INHIBITING DRUGS (BIOSPAN, TRIOSPAN). (Ger.) Vizi, E. S. (Med. U., Budapest) and P. Szentmiklósi. *Z. Aerztl. Fortbild. (Jena)* 61(7):353-358, 1967.

A combination of the properties of the ulcer-inhibiting compounds isopropamide and No-Spa, (6,7,3',4',-tetraethoxy-1-benzyl-1,2,3,4-tetrahydroisoquinoline), a compound less toxic than papaverine and more rapidly absorbed, was studied. The p.o./i.v. index for No-Spa is 14.0 and for papaverine, 33.9. Combining isopropamide and No-Spa did not increase the toxicity over that of the separate compounds and they retained the useful activities. When tested on Shay ulcer preparations the combination was superior to th single compounds. The effectiveness of a combination of 3 compounds was next tested: Isopropamide-No-Spa and Quietidin (not identifi Quietidin has anti-histamine, parasympatholytic spasmolytic, and tranquilizing actions. The properties of the combination of the 3 compounds, in terms of absorption, toxicity, etc., were not different from those of the single compounds when tested on animals. These combinations, Biospan (5 mg isopropamide plus 6 mg No-Spa) and Triospan (5 mg isopropamide plus 6 mg No-Spa and 60 mg Quietidin in tablet form were then tried clinically. After tests on a patient population which also contained cases o digestive tract disorders other than ulcers, i was concluded that Biopsan had the greatest therapeutic index, 26 times greater than atropi followed by Triospan when tested clinically fo over 6 mo. Biopsan had the least side reactio and also the best record for recovery or cure. In general, recovery was indicated by (1) fewe subjective complaints, (2) reduction or disappe ance of X-ray pathology, (3) gastric acidity normalized or significantly decreased, (4) increased body wt. of the patients.

9214 VITAMIN THERAPY OF PEPTIC ULCER. (Rus Shilov, P. I. (Milit. Med. Acad., Leningrad, USSR) and T. N. Iakovlev. *Klin. Med (Moskva)* 45(2):40-45, 1967.

Of 323 patients (274 men, 49 women; 127 of whom were under 30 yr. of age, and 196 of whom were over 30) with peptic ulcers (duodenal in 300, gastric in 23) of less than 1 yr. to more than 5 yr. duration, 237 received hormone therapy an 86 served as the controls. The av. duration of treatment for the hormone group was 37.1 days, and that of the controls was 43.1 days. Pain had disappeared after 1-2 wk. of treatment in 40% of the hormone group and 22.1% of the controls; a marked clinical improvement was obtained in 50.6% of those treated with hormone and in 43% of the controls, while partial improvement was observed in 48.1% treated with hormones and 53.5% of the controls. There was no effect observed in 1.3% of the hormone group and in 3.5% of the controls. Pain disappeared in 59 of 63 treated with ascorbic acid plus bioflavonoids (Group 1), in 66 of 75 treated with ascorbic acid and the vitamin B complex (Group 2), in 38 of 40 treated parenterally with thiamine (Group 3) and in 56 of 59 treated with thiamine and other vitamins (Group 4); in the remaining patients (18), pain was only reduced. The ulcer niche was closed in 26 of 63 patients of Group 1, in 27 of 75 in Group 2, in 12 of 40 in Group 3 and in 23 of 59 in Group 4; of the remaining 149 patients, the ulcer niche was decreased in 45, indirect signs were found in 75 and no data were available on 29 patients. A marked clinical improvement was found in 27 of 63 patients in Group 1, in 41 of

Group 2, in 21 of 40 in Group 3 and in 31
in Group 4. Partial clinical improvement
red in 36 of 63 in Group 1, 33 of 75 in
2, 19 of 40 in Group 3 and 26 of 59 in
4. No change was found in 1 of 75 in Group
59 in Group 4. The duration of treatment
oup 1 lasted 39.9 days; that in Group 2 was
days, Group 3, 35.3 days and Group 4, 35.2
It is concluded that vitamins have a
ive effect on the clinical course of
nts with peptic ulcers.

EARLY SYMPTOMS OF NEUROGENIC GASTRIC
WALL DYSTROPHY AND THE EFFECT OF NEURO-
C AGENTS. (Rus.) Zavodskaia, I. S. (Inst.
Med., Leningrad, USSR) and A. A. Manina.
. Eksp. Biol. Med. 63(3):75-78, 1967.

imental dystrophy of the gastric mucous
ane was provoked in immobilized rats with an
ric current and by traumatizing the duodenum.
croscopic changes in the gastric mucous mem-
, which were observed 1 hr. after a 15-min.
lation of adult rats, included altered
-structure of the chief and parietal cells.
were alterations in the endoplasmic
ulum with decreased content of ribosomes
lterations of destructive nature in mito-
dria; chief cell nuclei were increasingly
philic and had more pronounced condensation
cleoprotein granules than was normal. Thus,
croscopic changes reflecting disturbances
bonucleoprotein synthesis developed during
arly stages of dystrophy. Alterations in
e protein synthesis were accompanied by
ological disturbances of regeneration;
ed protein metabolism was studied by the
of incorporation of ^{35}S of amino acids.
oefficient of mitotic activity was changed
alteration of the various mitotic phases.
of transition of the cell from the inter-
ic condition into mitosis during ribo-
oprotein synthesis suggested a disturbance
is process. Three hr. after stimulation,
ic disturbances increased and were of a
tive local character; at this time,
biotic changes could even be observed by
microscopy. There was a clear vascular
ion, characterized by focal infiltrations
iapedesis. Hexamethonium prevented reflex
rophy only in a dose of 10 mg/kg, which
ed sympathetic ganglia. In addition,
atholytics and guanethidine were effective,
nting the development of neurogenic distur-
s. Electrical stimulation of the hypo-
amus produced destructive changes in the
ic mucous membrane in rabbits which were
ar to those already described. These de-
ctive changes could be prevented by resection
e vagus nerve below the diaphragm and by
reliminary admin. of phenobarbital.
ently, upon excessive stimulation of the
exogenic zone, the impulses, entering
gh the activated reticular formation, greatly
te the sympathetic centers, which are located
e hypothalamus. From this region the flow
of impulses pass by way of the sympathetic nervous system and produce alterations in the gastric mucous membrane.

9216 GASTRIC HYPOTHERMIA FOR DUODENAL ULCER. A LONG-TERM CONTROLLED STUDY. (E.) Harrell, W. R. (VA Hosp., Dallas, Tex.), H. Rose, J. S. Fordtran and B. Friedman. J.A.M.A. 200(4):290-294, 1967.

A total of 52 patients with active duodenal ulcer were randomly divided into 2 groups. The controls were "sham frozen"; this group consisted of 24 persons (23 males, 1 female) 30-84 yr. old, with an av. of 46.5 yr.; duration of ulcer symptoms ranged from 2-20 yr., with an av. of 11.7 yr.; 8 (33%) had previous hemorrhage, 2 (8%) had previous perforation; the av. basal acid secretion was 123 ml/hr. or 5.2 mEq/hr., and av. max. acid output was 298 ml/hr. or 29.2 mEq/hr. The hypothermia group received a standard gastric freezing procedure; this group consisted of 28 patients (27 males, 1 female), 22-67 yr. old, with an av. age of 43.4 yr.; duration of symptoms ranged from 1-30 yr., with an av. of 10.8 yr.; 14 (50%) had previous hemorrhage, 3 (11%) had previous perforation; the av. basal acid secretion was 116 ml/hr. or 4.6 mEq/hr., and the av. max. acid output was 305 ml/hr. or 31.8 mEq/hr. All patients were followed for a minimum of 18 mo.; both groups experienced symptomatic improvement. The degree and duration of symptomatic improvement was greater in the hypothermia group, and the results were statistically significant at 3 and 6 mo. Depression of basal acid secretion was transient, but significant depression of the max. acid output was observed after hypothermia, and this lasted for 6 mo. There was no correlation between clinical improvement and altered gastric secretory function. Antibodies against gastric mucosa were not demonstrated. While the benefits of gastric hypothermia appear definite, it is suggested that the brief duration of clinical improvement does not justify the use of this method.

9217 PARATHYROID FUNCTION IN PATIENTS WITH PEPTIC ULCER. (Pol.) Chojecki, Z. (Postgrad. Inst. Gastrology, Warsaw), K. Chrostowski and J. Dobrowolska. Pol. Tyg. Lek. 21(32):1220-1223, 1966.

Serum Ca, serum P and serum alkaline phosphatase were determined in 40 gastric ulcer patients, 40 duodenal ulcer patients and 20 controls. In addition, creatinine clearance, P clearance (C_p), phosphate excretion index, tubular reabsorption of phosphate, P glomerular filtration rate and serum albumin levels were determined in 20 gastric ulcer patients, 20 duodenal ulcer patients and 10 controls. The results of most of these biochemical tests were within normal limits. Serum Ca levels and serum P levels were within normal limits. Serum α_2- and β-globulin fractions were not elevated, indicating these patients were not hyperthyroid. Renal P clearance was increased in 30%, while tubular reabsorption of phosphate was decreased in 60% of the ulcer patients. The phosphate excretion index was elevated in these patients and in 15% was close to pathologic values. It is concluded that these disturbances of P metabolism in the kidneys are not sufficient proof of a relationship between parathyroid hyperactivity and peptic ulcer. It is assumed that some unknown biological factor influences the absorption of P in the renal tubules in peptic ulcer patients.

9218 THE ROLE OF DOSAGE FORM IN ASPIRIN-INDUCED GASTROINTESTINAL BLEEDING. (E.) Leonards, J. R. (Western Reserve U. Sch. Med., Cleveland, Ohio) and G. Levy. Clin. Pharmacol. Ther. 8(3):400-408, 1967.

Two types of aspirin tablets were used: A contained 0.32 g finely-milled aspirin (80 mesh or finer) per tablet; B contained 0.32 g relatively coarse aspirin (all particles greater than 20 mesh) per tablet. There were 6 healthy subjects in the absorption studies (5 females, 1 male, 23-41 yr. old, av. 28). Each received 2 tablets of Types A and B, resp., 1 wk. apart. The tablets were swallowed whole in 200 ml. water on an empty stomach in the morning; no food was taken for 2 hr.; blood samples were taken at 10, 20, 30, 60, 120, 240, and 360 min. after admin. the conc. of total salicylate in the plasma was determined and % of admin. dose at a given time was calculated from this. Gastrointestinal blood loss studies were made on 7 males and 5 females (19-32 yr., av. 24) with no history of gastrointestinal disease and with normal hematocrits. Venous blood (20 ml) was withdrawn from each subject, mixed with 10 ml (anticoagulant acid citrate dextrose) soln. containing 300 μc ^{51}Cr, and reinjected after incubation for 30 min. at 37°C. Stools were collected from 3-50 days and divided into six 8-day periods alternating control and tablet days. Blood in stools (ml) was calculated as (cpm/g stool homogenate)/multiplied by (cpm/ml blood) (wt. of stool homogenate). Subjects took 3 tablets (either fine, coarse, or placebo), 4 times a day, followed by 120 ml water. Aspirin in A tablets dissolved and was absorbed considerably more rapidly than that in B. There was significantly more gastrointestinal bleeding during admin. of aspirin than in control periods. There was no statistically significant difference in bleeding caused by the 2 types of tablets. There was a statistically significant correlation between normal blood loss in control- and placebo-admin. periods. Subjects who bled the most in control periods did not necessarily do so during aspirin admin.

9219 STRESS ULCERS: A SURVEY OF THE EXPERIENCE IN A LARGE GENERAL HOSPITAL. (E.) Grosz, C. R. (State U. New York, Brooklyn) and Wu, K-T. Surgery 61(6):853-857, 1967.

Case histories of 61 patients with upper gastr intestinal bleeding, and clinically demonstrat stress ulcers, but who were admitted for other conditions, were collected from 2346 case hist ies accumulated over a 5-yr. period. During t same 5 yr. covered by the histories, 352 stres (acute) ulcers were found at autopsy of 5669 patients, 188 males (126 gastric and 62 duoden and 164 females (118 gastric and 46 duodenal). Stress ulcers were most prevalent among patien 56-65 yr. old. It is concluded that the condi tion is more common than generally believed, a should receive aggressive prophylaxis.

9220 SIMPLE GASTRIC ULCER--A RADIOLOGICAL SURVEY. (E.) Cahill, P. (St. Vincen Hosp., Sydney, Australia) and W. B. Hennessy. Med. J. Aust. 1(5):166-169, 1967.

A study of 100 patients (69 women, 31 men) wit 107 ulcers revealed that peak incidence in wom occurred earlier (23% at 41-50 yr.) than men (13% at 51-60); overall peak incidence occurre at 41-50 yr. There was no sex difference in ulcer location. The main conc. of ulcers was found just below the junction of the middle- a upper-thirds of the stomach, and there was a smaller group of ulcers in the prepyloric zone Of the 107 ulcers, 81 (75%) occurred in the upper half of the stomach. The majority were situated on or adjacent to the lesser curvatur There were 29 giant ulcers (diameter greater t 3 cm), 18 in women, 11 in men. Distribution w essentially the same for both sexes, and the overall distribution of giant ulcers closely resembled that for the entire series.

7 STATISTICAL STUDIES OF THE INCIDENCE OF
INTESTINAL TUBERCULOSIS AND REGIONAL
ERITIS IN THE LIGHT OF IMPROVED DIFFERENTIAL
GNOSTIC CRITERIA. (It.) Bettinelli, G.
ggiore Hosp., Milan, Italy) and G. Cosmacini.
z. Int. Med. Chir. 72(6):505-512, 1967.

eview of the diagnostic records of a large
/ hospital showed that the recorded incidence
Crohn's disease, as compared to Koch's
ocecal tuberculosis, was 1:19 for the yr.
l-1945, inclusive. For the yr. 1961-1965, it
14:1. Review of X-ray and histopathologic
ords of the later group appeared to confirm
much of the difference might be due to
roved diagnostic technics and differential
gnostic criteria.

CROHN'S DISEASE. (Nor.) Gjone, E.
(State Hosp., Oslo). T. Norsk.
geforen. 87(9b):911-914, 1967.

ng the period 1956-1963, 73 cases were
lied varying by yr. from 4-16 with an annual
dence of 1.1-4.4/million population. Patients
ed from 10-79-yr. old with 58 being between
nd 59-yr.; 37 were males and 36 females.
ferent geographical areas showed differences
ncidence, varying from 1.9-3.5 in annual
dence/million population with an av. of
million population/yr. for all areas for the
od 1956-1963. Symptoms and some findings
: mild abdominal pain (in 42 cases); strong
minal pain (20); periodic fever under 38.5°C
; periodic fever 38.5°C and over (3); diarrhea,
than 5 stools/day (31); diarrhea, 5 or more
ls/day (7); definite weakness (29); occult blood
; macroscopic blood in the stool (2); subileus
); ileus (15); peritonitis (1); and palpable
ominal filling (26). Crohn's disease can be
alized in almost any region of the intestine.
these 73 patients, X-ray, operation or both,
ated the disease; in the ileum only (42); the
minal ileum and cecum (15); ileum and jejunum
; jejunum alone (5); the terminal ileum and
er parts of the colon except the cecum (5).
gle fistulas occurred in 15 cases to 5
ferent structures; 9 multiple fistulas were
nd to 2-5 structures each in a total of 11
uctures (such as rectum, vagina, etc.). These
ients were treated by (1) medicinal therapy
ne (15), 7 symptom-free, or better, 4
unchanged or worse, 3 dead, and 1 unknown; (2) primary resection (41), 34 symptom-free or better, 4 unchanged or worse, 3 dead; and (3) primary bypass (16), 3 symptom-free or better, 11 unchanged or worse, 2 dead. Although the total number of cases were few (73) it seems that treatment by resection is most favorable. Secondary infections must be treated and vitamin B_{12} inj. may become necessary.

9256 HISTOCHEMICAL LOCALIZATION OF INTESTINAL DISACCHARIDASES: APPLICATION TO PERORAL BIOPSY SPECIMENS.

(E.) Jos, J. (Hosp. Sick Children, Paris), J. Frézal, J. Rey and M. Lamy. Nature (London) 213(5075):516-518, 1967.

The technic of Dahlqvist and Brun is described. Intestinal biopsies was obtained from 4 normal children, 5 patients with sucrose and isomaltose intolerance, from guinea pigs, and rats. Chromogenic reagent was prepared by a soln. in phosphate buffer (pH 6.5; 0.1 M) with different reagents. Substrate soln. were made with palatinose, lactose or sucrose/ml of distilled water. Mounted sections were placed on a tissue culture vessel lid and a conc. soln. of glucose oxidase were put on each; they were then moistened with chromogenic reagent. The vessel containing chromogenic reagent and the appropriate substrate soln. was closed and incubated for 3-6 hr. at 37°C, giving brown stain. Some sections were treated before incubation with sulfhydryl inhibitors to inhibit nonspecific staining of sulfhydryl compounds. Results of this procedure were similar in normal human duodenal mucosa and guinea pig mucosa, whether maltose (giving a stronger reaction), palatinose or sucrose was used as substrate. The precipitate was accurately localized in the brush border of the villous epithelial cells, whereas staining was absent or weak, in the cytoplasm. No staining occurred in the crypts, but precipitate was found in some cells of the lamina propria. Trehalase activity was also intense in the brush border, but the reaction was rather localized near the tip of the villi. With lactose as the substrate, a stain was obtained in both the brush border and apical cytoplasm of the villous epithelial cells. Control sections of human and guinea pig material incubated without substrate gave consistently negative results, whereas rat sections incubated the same way developed a stain (nonspecific, blocked by previous treatment with p-chloromercuribenzoate) throughout the cytoplasm of the epithelial cells. Sections from tissue without disaccharidase activities failed to react significantly. Intestinal biopsies of patients with congenital sucrose and isomaltose intolerance had normal trehalase and lactase activities, but reacted weakly with maltose and not at all with sucrose and palatinose. This technic shows that the disaccharide-splitting enzymes are primarily, if not exclusively, localized in the brush border.

9257 GENETIC AETIOLOGY OF LACTOSE INTOLERANCE.

(E.) Ferguson, A. (Glasgow Roy. Infirm., Scotland) and J. D. Maxwell. Lancet 2(7508):188-190 & 191, 1967.

A 28-yr.-old male with diarrhea was found to have lactase (β-galactosidase) deficiency; his family (parents and 5 sibs) were investigated by lactose-tolerance tests and intestinal biopsy. Primary hypolactasia was found in 1 (28-yr.-old) sister, and a generalized disaccharidase deficiency (secondary hypolactasia), secondary to a collag disease, was found in another (32-yr.-old) sist In the proband, a biopsy specimen of the jejunu revealed normal mucosal histology and there wer no further symptoms after 4 mo. on a milk-free diet. The incidence of primary hypolactasia in 2 of 6 sibs with normal parents suggests that primary hypolactasia is hereditary, and that th pattern of inheritance is autosomal recessive.

9258 THE ULTRASTRUCTURE OF THE INTESTINAL MUCOSA IN CELIAC DISEASE.

(Ger.) Tichý, J. (Charles U., Hradec Kralove, Czechoslovakia), M. Hradský, V. Plachý and A. Peregrin Z. Ges. Inn. Med. 22(5):143-148, 1967.

Of 5 children studied, 3 had celiac disease, 1 had an acute attack 4 yr. before with recovery, and 1 had pneumonia without signs of malabsorpt syndrome. Jejunal mucosa biopsies were obtaine from the 5 patients, with the fifth as a contro the tissues were prepared for electron microsco In the 3 cases of celiac disease, changes were evident in the apical enterocyte organelles and in places of normal layering of the microvilli; the mitochondria were fewer and appeared withi the middle-third of the cytoplasm between the nucleus and the periphery. They were smaller than normal and the cristae presented a striate appearance. The cisternae of the endoplasmic reticulum were enlarged and more numerous. The intercellular spaces were widened and the basil membrane of the mucosa seemed to be thickened and infiltrated with plasma cells. These ultra microscopic changes were the same in the tissue of the 3 patients with acute celiac disease. T other constituent cell types of the mucosa, goblet cells, Paneth cells and argentaffin cell were in all cases normal and unchanged in appea ance. The patient that recovered from an acute attack 4 yr. previously showed some shortened, and some deformed, villi, as well as some empty spaces where villi had been. The enterocytes were richly supplied with mitochondria (more sc than the control); lysosomes were plentiful. These cells seemed cytologically normal.

9259 GALACTOSE MALABSORPTION IN THE ADULT.

(Ger.) Rommel, K. (Justus Liebig U., Giessen, Germany), K. Grimmel and E. Margolf. Klin. Wschr. 45(11):559-564, 1967.

In 3 patients with low or failing blood galacto levels (24 yr., 63 yr. and 34 yr. old) and no history of illness or present restricting condi tions, galactose loading tests (40 g galactose p.o.) were admin.; blood galactose levels were determined at 15-min. intervals up to 150 min., and also the galactose excretion after 3 hr. Glucose and lactose loading tests were also car ried out in 1 of these patients. Both glucose and galactose blood levels were determined at 15-min. intervals following the lactose loading

tase activity was measured in biopsies under
same conditions of conc. as obtained in the
estine. The determinations were made under
hly controlled conditions. The 24-yr.-old pa-
nt showed a peak blood level after oral loading
18-10 mg%; only 0.3 g% of galactose was excreted
the urine and lactase activity was normal. In
63-yr.-old subject peak blood galactose levels
e 14-17.5 mg% with urinary excretion of 0.3 g
er oral loading. Glucose-loading tests
g glucose each) showed normal increase of
od glucose from a fasting level of 120 mg% to
mg%. The 34-yr.-old subject had blood galac-
e peak levels of only 9-5 mg% after oral load-
while no galactose was found in the urine. In
24-yr.-old patient the amount of galactose
orbed from 40 g p.o. was 24% or just under 10 g,
reas an intraduodenal dose delivered by in-
ation (40 g) was 45% absorbed (18 g). Renal
eshold for galactose seems to be about 10 mg%
od galactose level. Lactase activity of the
denal mucosa was normal in those cases, there
a small amount of galactose excreted and
ifference existed between p.o. and intraduo-
al loading. Galactose metabolism is apparently
faulty. The difference between oral and duo-
al loading suggests some action of oral or
tric secretion upon galactose to impede its
orption.

0 STUDIES ON NUMBER AND SEPARATION OF ENZYMES IN THE MUCOSA OF THE GASTRO-
ESTINAL TRACT. PART I. THE NORMAL DISAC-
RIDASE CONTENT OF THE ADULT DUODENUM. (Ger.)

sen, H. T. (U. Kiel, Germany), H. C. Drube,
E. Klein and K. Zielke. Gastroenterologia
sel) 106(6):345-356, 1966.

psies (10 each) were obtained from the
erior-, median- and inferior-thirds of the
denum from 30 healthy subjects fasted for a
imum of 8 hr. and were obtained from the
denal bulb. The wt. of the mucosal biopsies
ied from 8-30 mg. They were frozen at -20°C;
ts showed no diminution of enzyme activity in
frozen tissues within 1 wk. The tissue was
ogenized in physiologic saline at low temper-
re; the homogenate was centrifuged; the super-
ant diluted according to the enzyme conc. (in
al runs) with 0.9% NaCl. The maltase, inver-
e, lactase, and cellobiase activities were
ermined at a pH of 5.8 with an incubation
iod of 60 min. at 37°C. The reaction was halted
placing the test tubes in a boiling-water bath;
glucose released from the specific disac-
ride was then determined. The enzyme activities
e expressed in U; one U of disaccharase activity
rolyzes 1 μM of substrate/min. (at substrate
c. of 0.028 M, 37°C and optimal pH). These U
then given/g of protein in the tissue. The
conc. for the 4 enzymes in descending order
magnitude was maltase invertase, lactase and
lobiase, for all duodenal regions. The conc.
all enzymes were least in the duodenal bulb
greatest in the inferior-third, gradually
reasing from the proximal to the distal end of
the duodenum (a slight variation in invertase occurred in the 2 middle positions. The av. number of U of lactase/g of protein were: duodenal bulb, 2.7; upper-third, 9.0; middle-third, 20.3; and lower-third, 46.6. In the lower-third the av. number of enzyme U for 10 individuals were: Maltase, 217.1; invertase 85.8; lactase, 46.6; and cellobiase, 11.6. A number of individuals showed considerable variation in values for 1 or more of the disaccharidases. Four with low av. for lactase had no milk intolerance.

9261 THE HISTOCHEMICAL LOCALIZATION OF INTESTINAL DISACCHARIDASES BY A NEW PROCEDURE. (Fr.)

Jos, J. (Hosp. Sick Children, Paris), J. Frézal, J. Rey, M. Lamy and R. Wegmann. Ann. Histochim. 12(1):53-61, 1967.

Biopsies of 15 children (1-8 yr. old) were tested for α-glycosidase activity; 6 had celiac disease with gluten intolerance, 5 had intolerances for saccharose and isomaltose, and 4 had other disorders but normal intestinal absorption. Intestinal samples of rat and guinea pig were tested by this method and compared to enzyme determinations made from tissue homogenates of the same intestines. The biopsies were immediately frozen in liquid N, sectioned, mounted on coverglasses and fixed in acetone at 4°C for 15 min. Each preparation was placed in a tissue-culture chamber with a layer of filter paper between the section and the soln. contained in the chamber; the coverglass rested upon the cover of the chamber. Three different soln. were used: 1) Phosphate buffer (pH 6.5 0.1 M) containing 5 mg/ml gelatin tetranitroblue-tetrazolium, 0.33 mg/ml, phenazine methosulfate, 0.05 mg/ml, and glucose oxidase, 0.2 mg/ml. 2) Four mg glucose-oxidase/ml of phosphate buffer (pH 6.5 0.1 M) only. 3) The individual soln. of disaccharides were each (100 mg/ml) in distilled water, except maltose (25 mg/ml) and trehalose (50 mg/ml). A drop soln. of (2) was placed on the section, the filter paper moistened with soln. (1) placed over the section, and 1 ml Soln. 1 and 0.1 ml Soln. 3 placed in the inverted chamber which was then closed, sealed and incubated 3-5 hr. at 37°C. A similar preparation, but with disaccharide soln. omitted, incubated for the same time, served as a control. Glucose, liberated by hydrolysis, caused a brown precipitate of formazan by reduction. The patients with saccharose intolerance had feeble saccharase activity, although the other enzymes were in normal conc. Those with celiac disease had a general deficit of all hydrolytic enzymes. The activity of α-glycosidases was localized in the brush border of epithelial cells.

9262 SERUM PRECIPITINS TO MILK, GLUTEN AND RICE IN TROPICAL SPRUE. (E.)

Bayless, T. M. (Johns Hopkins Hosp., Baltimore, Md.), J. S. Partin and J. C. Partin. Johns Hopkins Med. J. 120(5):310-316, 1967.

Subjects in Puerto Rico were divided into 4 groups: Group 1 consisted of 56 patients with untreated tropical sprue (16 mild, 23 moderate, 17 severe); Group 2A consisted of 30 patients from Group 1, restudied during complete or partial remission after treatment with folic acid (9), vitamin B_{12} (3), both (8), tetracycline (5), gluten-free diet (4), spontaneous remission (1); Group 2B consisted of 55 patients studied only after treatment with folic acid (14), vitamin B_{12} (4), tetracycline (3), a combination (34); Group 3 was composed of 9 patients with nonspecific self-limited diarrhea; Group 4 was composed of 104 (18-22 yr. old) normal controls. Precipitating antibodies to milk, gluten, wheat, rice and gliadin were identified by micro-immunodiffusion. Precipitins to one or more of the dietary antigens was found in 37.5% of Group 1 and in only 4.8% of the controls. The precipitins disappeared rapidly in most cases after therapy. Of 10 with serum precipitins after treatment, 9 had persistent steatorrhea and jejunal biopsy abnormalities. Antibodies in the sera of Group 1 and refractory Group 2 were probably due to increased permeability to dietary antigenic molecules of the damaged small intestine mucosa. These antigens, in turn, stimulated the demonstrated antibodies. The most frequently encountered antibodies were those to raw milk. There was no observed relationship between the presence of milk antibodies and symptoms of milk intolerance. In contrast to those with celiac disease, none of those with tropical sprue had precipitins to gliadin. It is concluded that precipitins to gliadin are characteristic of celiac disease.

9263 RAPID INTRAVENOUS SORBITOL LOADING TEST AND ITS "URINARY FRUCTOSE INDEX". PART I. URINARY FRUCTOSE CONCENTRATION IN A GROUP OF NORMAL SUBJECTS. (It.) Pannuti, F. (U. Bologna, Italy), O. Masiello, I. Spagna and V. Randi. Riv. Gastroent. 18(5):261-268, 1966.

Rapid i.v. sorbitol loading (1 ml of a 25% soln./kg body wt.) was performed in 20 normal subjects of both sexes (age 30-45 yr.), and urinary fructose conc. determined according to a modified Roe method every half-hr. for 4 hr. Av. urinary excretion of fructose was highest 0.5 hr. (38.471 μg) and 1 hr. (15.689 μg) after loading and lowest after 4 hr. (5.532 μg). In order to simplify matters and to provide a basic U for comparing urinary fructose values, the authors propose the use of an "urinary fructose index for sorbitol" (IFS) obtained according to the following formulas:

$$A_{mx} - B_{mm} = X \quad \text{and} \quad \frac{X \cdot T_{Bmn}}{1000} = \text{IFS}$$

where A_{mx} = max. conc. of urinary fructose; B_{mn} = min. conc. of urinary fructose; T_{Bmn} = time of B_{mn} (i.e., 30 min. = 0.5; 60 min. = 1; 90 min. = 1.5, etc.). Av. IFS was 122.71 in these patients; with 2 exceptions, values ranged from a min. of 103.87 to a max. of 153.7. Further application of the above test and proposed index to the field of human hepatic pathology will ultimately confirm their validity. The authors emphasize the importance of renal integrity inasmuch as the conversion of sorbitol to fruc at the urinary level involves the following 4 ponents: sorbitol, hepatic sorbitol dehydroge kidney, and urinary fructose. (See also #9264

9264 RAPID INTRAVENOUS SORBITOL LOADING T AND ITS "URINARY FRUCTOSE INDEX". P II. URINARY FRUCTOSE CONCENTRATION IN A GROUP SUBJECTS WITH HEPATIC CIRRHOSIS. (It.) Pannu F. (U. Bologna, Italy), I. Spagna, O. Masiello and V. Randi. Riv. Gastroent. 18(5):269-275,

Fifteen patients of both sexes (age 40-61 yr.) with clinical and laboratory evidence of hepat cirrhosis were subjected to rapid i.v. sorbito loading. Details of admin., collection of uri specimens, and urinary fructose determination are as described in the previous abstract. Av urinary excretion of fructose was highest 0.5 (23.53 μg) and 1 hr. (10.9 μg) after loading a notably lower than values observed in normal s jects for the same time periods. Minimum excr tion of fructose occurred after 3.5 hr. in pat with cirrhosis (6.64 μg) and after 4 hr. in no subjects (5.53 μg). The av. IFS (urinary fruc index for sorbitol) in cirrhotic patients was 54.21 as compared to 122.71 in normal subjects Among cirrhotic patients, only 2 had an IFS greater than 100. Although it is still too ea to affirm the clinical value of the above test and index system, results in this study differ clearly from those observed in normal subjects (See also #9263)

9265 LIVER ALDOLASE IN FRUCTOSE INTOLERAN (Fr.) Schapira, F. (Hosp. Sick Chil Paris) and J.-C. Dreyfus. Rev. Franc. Etud. C Biol. 12(5):486-489, 1967.

Biopsies of liver weighing 3-15 mg were immedi frozen; after homogenization in 30-100 vol. of ice water, activities of the aldolases were de mined by colorimetry. The activities of fruct kinase and glucose-6-phosphatase were also established. Results were reported in I.U. Li samples were obtained from 12 children with fructose intolerance, from children with norma fructose tolerance, and from embryonic and fet livers as soon as possible after death. Cryst line rabbit muscle aldolase was prepared for comparison. Inhibition of the aldolases by adenosine triphosphate (ATP) was studied in al samples. Antiserum developed in the hen was u for studies of inactivation of the aldolases. Activities of the normal livers in I.U. for fructose-1,6-phosphate aldolase were 8-14, for fructose-1-phosphate aldolase, 8-14; the ratio individual livers, fructose-1,6-phosphate aldo over fructose-1-phosphate aldolase equaled one The av. activities of liver from 12 children with fructose intolerance were for fructose-1, phosphate aldolase, 2.07, for fructose-1-phosphate aldolase, 0.408 and the ratio of the av. 5.5. Fructokinase and glucokinase activities the intolerant were normal or close to normal. The activity ratio of the fructose intolerant

ater than that of human fetal livers (2-4 mo.)
ch ranged from 2-3. Inhibition by adenosine
phosphate of the liver aldolases of the fructose
olerant (30%) was almost equal to the av. for
nal human liver aldolase (12%) and human muscle
olase (45%) or to the av. of ATP inhibition
aldolases in rabbit liver (5%) and rabbit muscle
%) for that matter. Inactivation of the same
ymes by the antiserum of the hen was of the
e order. These results suggest 2 possible
nogenic mechanisms: 1) the persistence of a
atively high level of the embryonic aldolases;
2) a mutation repressing the aldolases which
ntually normally become predominant.

IMMUNOLOGIC PROBLEMS IN CELIAC DISEASE
AND THE INTOLERANCE TO COW'S MILK IN
LDREN. (Fr.) Lalande, J.-A. (Broussais Hosp.,
s), B.-N. Halpern, N.-T. Ky, J. Frézal and
Rey. Rev. Franc. Allerg. 7(2):65-75, 1967.

dren (66, up to 4 yr. of age) without any
estive tract disorders and with no history of
rrhea or dehydration served as controls in
se immunologic tests. Children with celiac
ease (29) and intolerance to cow's milk (6)
e tested by a specific, passive hemagglutination
t for the presence and levels of antibodies
inst gliadin and against the proteins of cow's
k. The specific antigen was fixed on rabbit
by the benzidine reaction; the degree of
agglutination produced by the addition of
um containing antibody was quantitative and
roducible. Antigenic rabbit blood specific
gliadin of wheat, casein of milk, α-lactalbumin,
actoglobulin, bovine serum albumin and bovine
unoglobulins and specific for the soluble
ctions was developed. Among the controls
ibodies were found in 4 children 6-18 mo. old
inst gliadin. Only one of the controls pos-
sed antibodies against cow milk casein. Anti-
es against the "soluble fractions" were found
3 of 25 cases. Antibodies against β-lacto-
bulin were found in 4 of 6 cases. In the celiac
ease group, antibody titer against gliadin
highly significant in 15 of 29 cases. Six
e followed after ommission of gliadin from
diet; 3 showed progressive decrease in anti-
y titer; two had retained very high antibody
r. Hemagglutinations were positive in one
ent with celiac disease against casein and
inst the "soluble fractions" in 12 of 15
dren; 6 had antibodies against β-lactoglobulin.
the 6 with intolerance to cow's milk, 3 had a
um antibody titer against casein; all showed
gh titer, 1/512 or greater, against the
uble fractions". The titer against β-lacto-
bulin was always constant. No antibody against
adin was found in these 6 cases of milk in-
erance.

LACTOSE INTOLERANCE IN HEALTHY CHILDREN.
(E.) Huang, S. S. (Johns Hopkins U.
Med., Baltimore, Md.) and T. M. Bayless.
Eng. J. Med. 276(23):1283-1287, 1967.

Caucasian and Negro children (20 each and between 11 mo. and 11 yr. of age) were studied. Milk-induced symptoms and positive family histories of milk and lactose intolerance were more frequent in Negro children; milk intolerance in 14 of the 20 Negroes and in 2 of the 20 Caucasians. Three Negro and 1 Caucasian child had histories of abdominal cramps following milk ingestion. Lactose loading caused abdominal discomfort in 7 Negroes and 2 Caucasians, including the 4 with milk intolerance. Peak levels of blood sugar with the lactose tolerance tests were less than 26 mg% in 7 of the 9 children with intolerance, and in 1 of the 31 lactose-tolerant children. Glucose-galactose tolerance was normal. It is concluded that lactose intolerance probably reflected intestinal lactase deficiency in most of the children studied. A gradual decrease of lactase activity after weaning was suggested by the fact that lactose-induced symptoms increased with age in both Negro children and Negro adults. Racial differences noted in this study are said to be consistent with the hypothesis that an hereditary intestinal lactase deficiency underlies the milk intolerance found in some adults.

9268 AN IMMUNOLOGIC STUDY OF CELIAC DISEASE WITH REFERENCE TO 38 CASES. (Fr.)
Roy, C. (Hosp. Sick Child., Paris), J. Lalande, J. Frézal, J. Rey, M. Lamy and B. Halpern. Path. Biol. (Paris) 15(7-8):384-390, 1967.

Circulating antibodies against gliadin and other food proteins were determined in 38 children with celiac disease, 170 normal children without any history of intestinal disorders, 18 convalescents of gastrointestinal fever and 6 children with intolerance to cow's milk. Tests (151) were made in 18 families of the 38 children with celiac disease; 8 families were studied in particular. The antibody level was determined by a quantitative passive hemagglutination technic. Used as antigens were: An alcoholic extract of wheat gluten suspended in glycerol, a protein extract from rice, a β-lactoglobulin preparation, and casein prepared by acid precipitation. Both casein and β-lactoglobulin were preserved after lyophilization of this preparation. In 11 cases (6.5%) some agglutination occurred with gliadin among the 170 controls; only 1 of 89 tested had some antibody conc. against β-lactoglobulin. Some reaction against the rice proteins (3% or less dilatation) occurred in 52 of 55 children studied. No increase of antibody levels against gliadin were observed in the 18 who recovered from gastrointestinal fever or in the 6 children with intolerance to cows' milk. The patients with celiac disease had changing levels of antibodies against gliadin depending, upon the duration on gliadin-free diet. Eleven were examined before treatment: 6 had antibodies against gliadin, 4 of these with very high titers; 2 had antibodies against β-lactoglobulin and casein and 1 against rice protein. Antibody titers against gliadin occurred in 15 others in the group, 11 of them were very high; 4 of 20 had β-lactoglobulin antibodies, and 3 of 21 had antibodies against casein. After 3 mo. on a gliadin-free diet, only 1 of 15 who had had antibodies against gliadin still exhibited antibody reaction. The antibodies against the other food proteins showed a corresponding decrease with time of abstinence. Reintroduction of the specific proteins showed that the antibodies against gliadin appeared more rapidly than the other antibodies, suggesting a different mechanism of formation. In some families of the celiac disease patients members had antibody titers against gliadin; in other families no antibodies were discovered.

9269 FAT ABSORPTION BY THE SMALL INTESTINE OF X-IRRADIATED MICE. (E.) Dulcino, J. (Ctr. Study Nucl. Energy, Mol, Belgium), J. R. Maisin and J. Deroo. Int. J. Radiat. Biol. 12(1): 93-96, 1967.

Mice were given either a diet of 5 parts of condensed milk 1 part of water and 1 part of salad oil or a fat diet of 20 ml of salad oil and 500 mg tripalmitate or palmitic acid. ^{14}C-Glyceryl-tripalmitate (0.5 μc) or palmitic acid (0.5 μc or 1 μc ^{3}H) made up 0.2 ml of these diets. To avoid gastric retention in the irradiated mice the diet was inj. directly into the duodenum after laparotomy. For each diet 4 groups of mice were tested: 1) controls; 2) controls inj. with 8 aminoethylisothiuronium-Br-HBr (AET); 3) irradiated mice; and 4) irradiated mice inj. with AET 10 min. before irradiation. Mice were irradiated 3 days before inj. of diet with 1500 r of X-rays at a dose rate of 100 r/min. Subsequently, it was found that the type of diet (low or high fat content) did not affect the results. No difference was noted between Control Groups 1 and 2. Animals were killed at 4, 8, and 24 hr. following admin. of diet. The gastrointestinal tract was excised, opened and washed with physiological saline. Percentage absorption was calculated from the sum of the activities of the luminal contents and feces. Total activity of the gastrointestinal wall was determined in a liquid scintillation counter after digestion in hyamine hydroxide at 65°C. Glycerides, phospholipids and fatty acids were assayed by chromatography of extracts of the intestinal contents, feces, and gastrointestinal wall. Three days after a dose of 1500 r X-rays no significant difference existed with respect to absorption of ^{14}C-palmitic acid or of glyceryl-tripalmitate-1-^{14}C, or of ^{3}H-palmitic acid. More ^{14}C-labeled fatty acids were present at 6 hr. in the wall of the small intestine of the X-irradiated mice than in that of the non-irradiated controls; the mice protected by AET before irradiation had values for ^{14}C-labeled fatty acids in the intestinal wall intermediate between those of normal and irradiated nonprotected mice. By contrast, more ^{14}C-labeled triglycerides were found in the intestinal wall of the control than of the irradiated mice. ^{14}C-Labeled triglyceride levels of the protected irradiated mice were close to those of the intestinal wall of the controls. No differences were found with respect to phospholipids between groups. Intestinal contents showed a significant increase in triglycerides and phospholipids and a decrease in fatty acids after irradiation.

9270 ABNORMAL BILE-SALT PATTERNS AND INTESTINAL BACTERIAL OVERGROWTH ASSOCIA WITH MALABSORPTION. (E.) Rosenberg, I. H. (Boston City Hosp., Mass.), W. G. Hardison and D. M. Bull. New Eng. J. Med. 276(25):1391-1397 1967.

Thin-layer and gas chromatographic studies, per mitting accurate separation and estimation of conjugated and unconjugated bile salts, were us in this study of 2 men (59 and 65 yr. old) and 12 controls to learn whether unconjugated bile salts participate in the pathogenesis of the ma absorption syndrome which is seen in the presen of bacterial proliferation in the upper small intestine. The 2 patients presented with steat rhea and considerable bacterial overgrowth in t upper small intestine. Unconjugated bile salts in the intestinal fluid were identified as unconjugated cholic acid, deoxycholic acid and chenodeoxycholic acid although the conc. of unconjugated bile salts was low (rarely more thar 10% of total), the deoxycholic conc. in 1 patient was similar to the amount reportedly four to be toxic to intestinal transport processes in vitro. Conjugated bile salts were metaboliz when incubated with jejunal fluid from these patients, with in vitro degradation of 60-80% the total content of ^{14}C labeled taurocholate, as compared to degradation of only insignificar amounts of taurocholate by intestinal fluid der from normal controls. Erythromycin therapy improved absorption of both fat and vitamin B_{12}, and also resulted in the disappearance of unconjugated salts from the jejunal fluid, which was no longer capable of degrading taurocholat in vitro.

9290 RADIOLOGIC ASPECTS OF INTESTINAL TUBERCULOSIS LOCALIZED IN THE ILEOCECAL TRACT AND COLON. (It.) Martinotti, G. (U. Parma, Italy), A. Cugini and G. Savino. *Riv. Pat. Clin. Tuberc.* 40(1):22-48, 1967.

The radiologic aspects of 7 personally-observed patients with intestinal tuberculosis subsequent to pulmonary tuberculosis are described. Group 1 comprised 4 patients observed in a period prior to the advent of chemo-antibiotic therapy. The principal radiologic findings consisted of: prevalent hypotonia of the ileal tract; irregular mucosa pattern with numerous areas indicating possible ulcerations; canalicular aspect of the terminal portion of the ileum with irregular contours and tortuous course; characteristic cone-shaped appearance of the cecum with retraction of the medial portion; irregular mucosal pattern of the cecum and colon; stenosis of the distal portion of the ileum; concentric, opaque bands around the medial margin of the cecum due to infiltration and ulceration of the ileocecal sphincter. At surgery, these patients showed ileocecal tuberculosis with ulcerocaseous, hyperplastic, pseudopolypous lesions and with internal fistula (1) or tuberculoma (1). Group 2 comprised 3 patients with tuberculosis of the intestine who had been treated with various chemotherapeutic agents and antibiotics. Here the radiologic findings are more individual and evident since they are not masked by inflammatory signs. Characteristic signs are ulcerative forms in an early stage without diffuse spread and the presence of tuberculomas or vegetations of modest size without marked deformation of the gastrointestinal tract.

9291 STUDY OF LARGE INTESTINE TUMORS BY BARIUM ENEMA. (Fr.) Candardjis, G. (U. Lausanne, Switzerland). *Schweiz. Med. Wschr.* 97(18):577-585, 1967.

Patients undergoing Ba enema examination are prepared by 2-3 days of a low-residue, semiliquid diet, followed by laxatives, before admin. of a dilute Ba suspension; both laxative and Ba suspension contained tannic acid (0.25% and 0.5%, resp.). Moderate distention of the colon with diluted Ba, continuous fluoroscopic control of the progression of the suspension, high-kilovoltage radiography (125-150 kV), and photography from several angles to visualize all portions of the colon without superposition, were used. Suspicious regions were photographed again with and without compression. The double contrast method was used only as a complementary procedure. The radiological appearances of small polyps, vegetating carcinoma, amebiasis, schistosomiasis, endometriosis of the colon, extrinsic tumors, radiation-induced lesions, short areas of stenosis, and the residual areas after colon resection are discussed, with several illustrations.

9292 THE DANGER OF HYDROGEN PEROXIDE AS A
COLONIC IRRIGATING SOLUTION. (E.)
Danis, R. K. (St. Louis U. Sch. Med., Mo.),
A. E. Brodeur and J. Shields. *J. Pediat. Surg*
2(2):131-133, 1967.

Evidence is presented which indicates that maj
O_2 embolism had occurred in an infant followir
irrigation of the distal colon with 15-20 ml c
dilute hydrogen peroxide. Within 2 min. cyanc
and swelling developed over the lower trunk ar
lower extremities. X-rays illustrated gross
filling of the hepatic portal system with gas.
The blood pressure was 50/0 and the pulse,
160/min. Bacteremia followed: blood cultures
grew *Escherichia coli* and *Pseudomonas aerugino*
Specific antibiotic and supportive treatment
resulted in complete resolution. Laboratory
studies with 10 dogs confirmed this clinical
impression of massive O_2 embolization with
temporary portal venous obstruction. Radio-
graphic studies on the isolated liver of these
animals following irrigation with 30-50 ml of
1% hydrogen peroxide showed air bubbles in the
mesenteric veins and lymphatics within 1 min.
the instillation of hydrogen peroxide which
persisted for 30 min. During this period, po
venous pressure rose from a normal of 2-3 mm
to 40-50 mm Hg. Roentgenogram of the excised
liver showed a clear outline of the portal
venous system filled with O_2 emboli. Inj. of
the biliary tree with 50% Hypaque showed the
gas to be outside the biliary tree.

9293 4-HYDROXY-3-METHOXYMANDELIC ACID (HM
IN THE URINE OF NORMAL AND FASTING S
JECTS AND IN PATIENTS WITH COLITIS. (E.)
Goodman, I. (Columbia U., New York City), A.
Olenczak and R. B. Hiatt. *Clin. Chim. Acta*
16(2):245-248, 1967.

An improved method for the assay of 4-hydroxy
methoxymandelic acid (an end product of cate-
cholamine catabolism found in elevated levels
pheochromocytoma and neuroblastoma) using pap
electrophoresis followed by two-dimensional
chromatography (butanol:pyridine:water, 5:3:3
butanol:acetic acid:water, 120:30:50) is de-
scribed. Urinary levels (1.3 µg/mg creatinin
from 27 humans on a varied diet were 25% great
as determined by this method than those in the
literature. In fasting subjects, the urinary l
of this compound, if present at all, was below
limits of detection. Mean urinary level for 8
patients with colitis was 1.0 µg/mg creatinine
Normal levels (2.0 µg/mg creatinine) were obta
in patients with pheochromocytoma and neurobla
but larger amounts of unidentified compounds w
observed. The results support the suggestion
the urinary presence of this compound in human
is dependent upon food intake, but a metabolic
role for it is not excluded.

INTRAPERITONEAL DRAINS IN SURGERY OF
THE COLON. CLINICAL EVALUATION OF 454
;. (E.) Berliner, S. D. (Long Island
;h Hosp., N. Y.), L. C. Burson and P. E.
Amer. J. Surg. 113(5):646-647, 1967.

;4 consecutive colectomies there was a
ficantly higher morbidity in patients with
leakage than in those without drainage. In
ients without drainage in whom an anastomotic
developed there was a single death. Among
ients with leakage who had i.p. drainage
were 3 deaths. Patients with extraperitoneal
age had anterior resections and the 10%
ence of leakage in these patients was not
kable. Leaks occurred almost as often in
nts with i.p. drainage and overall mortality
lmost 3 times greater than in the group
ut drainage. When an anastomotic leak
oped there was no mortality among patients
extraperitoneal drainage, 11% mortality in
patients without drainage and a 60%
lity among those with i.p. drainage.
peritoneal drainage appears to serve as an
ate vent when leakage occurs in an anterior
tion. In patients with i.p. drainage who
leakage the drain does not often often func-
effectively and the mortality is high.
clinical results resemble those obtained
e laboratory. An i.p. drain will not pro-
the suture line from leakage, it need not
nt a diffuse peritonitis and by its inter-
ion the drain may keep adjacent omentum or
tine from sealing an anastomotic leak.

USE OF CIRCUMFERENTIAL TANGENTIAL
CRYOSTAT SECTIONS OF THE INTESTINE IN
IAGNOSIS OF HIRSCHSPRUNG'S DISEASE. (E.)
, J. L. (Child. Hosp., Sheffield, England),
nch and J. Lister. J. Clin. Path. 20(3):
66, 1967.

hod is described for making cryostat sections
ctal or colonic biopsy specimens received
tly from the operating room and derived
patients with suspected congenital mega-
. Small liver slices, obtained from rou-
necropsies, were frozen onto the ends of the
chucks with cardice, ahead of time, and
iver cut down until the surface had the
ur of the cut of the microtome knife and
bsolutely smooth. Sections of the sample
e, approx. 1 cm^2 and cut in a direction
lel with the main muscle layers, were then
ed onto the cut surface of the frozen liver,
ose surface they froze immediately when the
was kept in cardice. The chuck was then
ted on the microtome so that the plane of
f the knife was exactly parallel to the cut
surface, prior to making repeated, serial
ons through the intestine at 10-15 μ and
g them off onto numbered cover glasses.
mens for immediate diagnosis were either
ned directly or after staining with
hrome Cyanin R.S. (0.2 g in 0.5 ml conc.
iluted with 95 ml distilled water and 5 ml
1% iron alum). An additional staining technic, which permitted more definitive study, involved incubation of the same cryostat sections with acetylthiocholine iodide as substrate, permitting enzymic hydrolysis of the carboxylic acid ester of thiocholine sulfate in the presence of a cupric ion complex, followed by precipitation of the liberated thiocholine sulfate as a copper mercaptide, made more conspicuous by treatment with dilute ammonium sulfide. Instead of a normal ganglionic plexus, consisting of a groundwork of nerve cells in which the nuclei stand out as pale, unstained areas, "aganglionic" bowel sections treated by this method showed large, deeply stained nerve trunks, forming a very conspicuous, coarse, irregular network.

9296 THE USE OF Althaea officinalis ROOT IN X-RAY INVESTIGATION OF THE LARGE INTESTINE. (Rus.) Perepelkin, B. G. (Kuibyshev Med. Inst., USSR). Klin. Med. (Moskva) 45(2):57-63, 1967.

The large intestine was examined in 140 patients with a Ba suspension which contained Althaea root extract (10 g for adults, 5 g for children) and the subsequent admin. of air. The Ba suspension of the contrast enema was prepared in the following manner: Althaea root extract powder was dissolved in 30-40 ml of warm water and then Ba (100 g) and 80-100 ml water were added; the amount of Ba gradually reached 400-500 g. After obtaining a creamy mass, the mixture was diluted with a regular Ba suspension (400 g Ba/1.5 liters of water); this was boiled and cooled to 37°. In this manner the conc. of Ba was doubled, improving the quality of the X-ray and increasing its contrast. Althaea facilitated a better adherence of Ba to the intestinal wall, thereby significantly facilitating detection of the smallest formations on the intestinal mucous membrane, including those with a diameter of 0.1-0.2 cm. This method provides a max. economy of the X-ray film and time of examination, and affords images of polyps in all sections of the large intestine. No side effects were attributed to the extract. This procedure also enhances recognition of villous and carcinoma tumors since it permits study of the thin structure of the surface of the neoplasms. Two case histories are given in detail.

9297 TRANSRECTAL NEEDLE BIOPSY OF EXTRARECTAL MASSES. (E.) Anderson, M. J., Jr. Surg. Clin. N. Amer. 47(4):989-997, 1967.

A total of 52 transrectal needle biopsies were performed on 48 patients with extrarectal masses which were not thought to have prostatic origins; correct diagnoses were obtained in 40 (77%) cases, and presumably repetition of the procedure would have afforded correct diagnosis in 10 more. The successful biopsies gave significant therapeutic guidance in all cases, and no important complications occurred. The findings of rectal biopsies were tabulated into 4 groups. In Group 1, distinguished by presence of a rectal shelf, 22 procedures were performed on 20 patients; histologic diagnosis was correct in 16; in 3, subsequent findings showed that a benign histologic diagnosis was incorrect. In Group 2 (possible local recurrence after surgery for carcinoma of the left colon or rectum), 12 procedures were done on 10 patients; the diagnosis was correct in 8. Within this group there were 4 false negatives, benign diagnosis later disproved. In Group 3 (extrarectal masses after malignant disease had been treated in other body regions), 8 procedures were performed on 8 patients; 6 resulted in correct diagnosis, all malignant. The other 2 were false negatives. In Group 4 (miscellaneous extrarectal masses of uncertain diagnosis), 10 biopsies were done on 10 patients; the tissue diagnoses were correct in each case. Histologic study revealed malignancy in 7 and benign conditions in 3. By this method correct diagnoses were obtained in 40 (77%) of 52 instances. The technic of transrectal needle biopsy of extrarectal masses is described in detail.

9298 APPENDICITIS. AN ANALYSIS OF TWO THOUSAND ONE HUNDRED SEVENTEEN CASES TREATED SURGICALLY IN A COMMUNITY HOSPITAL DURING A PERIOD OF TWENTY YEARS. (E.) Magee, R. B. (Altoona Hosp., Pa.), J. M. Stowell and R. C. MacDuffee. Penn. Med. 70(6):47-49, 1967.

Group 1 (inflamed) included histologic diagnosis of subacute, acute, acute suppurative, acute fibrinopurulent with periappendicitis, gangrenous and perforated. The noninflamed, Group 2, included tissue diagnosis of normal appendix, atrophic appendix and appendix with lymphoid hyperplasia. Those in Group 1 had a shorter duration of symptoms (36.6 hr.; 48.6 hr. for Group 2), a lower right quadrant onset (42%; Group 2, 59%), a lower right quadrant localization of pain and tenderness (71%; Group 2, 58%), and no localization of pain in 25%. The most typical feature in Group 1 was a shift of pain from anywhere to lower right quadrant (38%; Group 2, 24%). Previous similar attacks occurred in 42% of Group 1, 26% in Group 2. The groups could not be distinguished on the basis of direct tenderness, nausea or vomiting, constipation, or diarrhea. Rebound tenderness favored a diagnosis of inflammation in the appendix. Frequency of normal peristalsis was 52% in Group 1, 60% in Group 2, while that of hypoactive peristalsis was 42% and 27%, resp. WBC and segmented neutrophils increased with severity of disease, while lymphocytes decreased. For normal, subacute, acute, gangrenous and perforated, the 3 hematologic values, resp., were: 12,605, 15,800, 16,550, 18,085, 18,325; 71.6, 74.5, 76.1, 80.5, 81.7; 23.1, 18.8, 15.6, 13.6, 12.6. A 20% incidence of albuminuria was characteristic of both groups. WBC in the urine (more than 3/high power field) occurred in 15% in Group 1, 1.8% in Group 2. Of 29 X-rays in Group 1, 40% showed abnormality suggesting peritoneal irritation. In Group 1, appendectomy was performed 77% of the time, appendectomy + drainage in 17.5%, drainage only in 2.5%. In 1955-1964 there was a 30% increase in preoperative use of antibiotics. In tissue diagnosis, the appendix was acutely inflamed in 66%, gangrenous in 13%, perforated in 3%, subacute in 6%, noninflamed in 12%. In 1945-1954, 22% of appendices removed were normal; in 1955-1964, 7%. The wound infection rate was 50 for perforated, 20% for others in Group 1, none for Group 2. The crude mortality rate was 0.6% 1945-1954, 1.3% in 1955-1964; corrected rates were 0.5% and 0.9%, resp.

9299 THE QUESTION OF EARLY OPERATION FOR APPENDICITIS. (Ger.) Prinz, P. (Crivitz/Mecklenburg Hosp., Germany). Zbl. Chi 92(15):546-550, 1967.

Appendicitis was studied in a total of 852 cases. Of 726 patients operated upon early within 48 hr. of onset, 673 definitely had inflammatory signs (including 29 perforations), 50 showed no macroscopic signs of appendicitis, 2 had ovarian cysts and 1 presented a stomach perforation. In 103 operated upon 3-5 days after beginning of symptoms, the disorder prove to be certain in 94; no inflammation was found in 9 cases. In the 23 undergoing late surgery, the clinical diagnosis was proven in 18 instanc Of the total 852 cases, clinical diagnoses were correct 785 times and the mortality rate was 0.32%. This rate was least in the group operat upon early; therefore early surgery is necessar Mortality rates published on over 70,000 cases of appendicitis (general mortality 0.7%; simple acute appendicitis, 0.13%) agree with this statement. Diagnostic accuracy is highest in the early stage, the risk increases with time, and medical treatment, chemotherapeutics, antibiotics and prednisone can often cause a distorted picture of the inflamed appendix.

9300 BLOOD COAGULATION AND ANTICOAGULATION SYSTEM IN PATIENTS WITH ACUTE APPENDICITIS BEFORE AND AFTER THE OPERATION. (Rus.) Alimov, T. U. (Tashkent Med. Inst., USSR). Khirurgiia (Moskva) 43(3):84-88, 1967.

In the majority of 101 patients (70 women, 31 men; 15-90 yr. old) with acute appendicitis, prior to surgery normal values were found for prothrombin, plasma tolerance to heparin, recalcification time, thrombo-test, heparin time, proconvertin and clot retraction. In half the cases, fibrinogen was increased, and i almost half of the cases, fibinolytic activity was less than 14%. During surgery, performed on 97 patients, prothrombin, proconvertin, heparin time and thrombo-test were normal in most of the patients, while there was a decreas in anticoagulant activity of the blood and the following parameters were accelerated: blood coagulation, plasma tolerability to heparin, calcification time, proaccelerin, fibrinogen d fibrinolytic activity. Repeated examination blood coagulation components after surgery vealed a regular acceleration of the blood agulation time, and an increase of fibrinogen dependent of the form of appendicitis (simple catarrhal in 37, phlegmonous in 40 and ngrenous in 20). An increased plasma toler- ility to heparin, thrombotest, and increase in othrombin, proaccelerin and acceleration of calcification time of the plasma were more ten seen in destructive forms of acute appendicitis, especially in aged and senile persons. anges in the coagulogram were dependent on the rm of the inflammatory process, duration of the sease, age, general condition of the patient, mplications and accompanying diseases. The nctional activity of the anticoagulation system s markedly decreased (a decrease of free parin conc. and fibrinolytic activity) in tients with acute appendicitis, especially ring severe involvement of the abdominal cavity. e serum Ca, amount of thrombocytes and duration hemorrhage were unchanged when compared before d after surgery. At 9-14 days after surgery, the majority of patients without complications, e blood coagulation indices, except fibrinogen d fibrinolytic activity, approached the lower mits of normal; fibrinogen remained elevated 57 and fibrinolytic activity decreased in 56. stoperative complications included thrombo- lebitis (1), wound pyosis (3), cardiovascular sufficiency (2) and pneumonia (1). A total of received postoperative prophylactic anti- agulant therapy, and these showed a decrease in e level of prothrombin activity to 35-40% of rmal.

01 THE INNERVATION OF THE MUCOSA OF THE HUMAN ILEOCECAL APPENDIX. (Fr.)

n Campenhout, E. (U. Louvain, Belgium), J. emers and J. M. Jadin. Rev. Canad. Biol. (2):95-107, 1967.

e study was done on 25 appendices; 8 acute, 12 bacute, 3 chronic cases, and 2 cases of per- ration. The temperature of the appendices was duced to 4°C quickly; pieces were fixed in 1% ffered OsO_4; others were fixed in Bouin's soln. ssues were studied by conventional and ultra- croscopy. Some silver impregnations with iline-blue trichromic stains (optical micro- ope) were particularly successful. Networks nerve fibers of the mucosa of the human pendix were precise in distribution and struc- re seen in the optical microscope and con- rmed by electron microscopy. No instance of nervation of the mucous epithelial cells was served in the sections from the 25 appendices. neural terminations of any kind were seen. particular differences in structure of the ural networks in the different appendices were ted. Only in a few cases was there evidence hyperplasia of the neural fibers at the base the glands of Lieberkühn.

9302 SIGMOID MYOTOMY IN DIVERTICULOSIS.

(E.) Dick, E. T. New Zeal. Med. J. 66(415):163-166, 1967.

Of 6 cases presented, 4 were treated for increasing severe constipation. In only 1 (62-yr.-old male with 2-yr. history of constipation) was there X-ray evidence of established diverticulosis. A 49-yr.-old female constipated for 3 yr. showed Ba enema X-ray evidence of prediverticular changes only in the sigmoid intestine with greatly increased irritability. In both of these, sigmoid myotomy was performed and good results were reported at 11 and 10 mo., resp. One case (a 59-yr.-old male with acute diverticulitis and bloody diarrhea) showed diverticulosis and diverticulitis with narrowing of the sigmoid intestine; 8 mo. after operation, the intestinal spasm was relieved but diverticulosis was still present. A 64-yr.-old male with chronic disabling constipation had a normal Ba enema X-ray. Sigmoid thickening was corrected and an unrelated small intestinal obstruction was corrected 1 wk. postoperatively, with good results at 7 mo. A 59-yr.-old female of spastic colon with diarrhea and intestinal colic, operation produced relief of colic, but not of diarrhea. Operation consists of incision along the longitudinal anti-mesenteric taenia and division of the circular muscle fibers down to mucosa so that the mucosa pouts into the longitudinal incision in the intestinal wall. It is suggested that development of diverticulosis probably follows increased intraluminal pressure and that it is reasonable to operate before diverticulosis or its complications become established in cases where intestinal disturbance is marked.

9303 INQUIRY INTO THE RESULTS OF SURGICAL TREATMENT OF CANCER OF THE RECTUM.

(Fr.) Peycelon, R. (Fac. Med., Lyon, France), X. Delore, Y. Jegou and R. Correard. Lyon Chir. 63(3):374-401, 1967.

Results are examined of 372 operations for cancer of the rectum, done by 3 different methods: 164 by perineal amputation (99 men and 65 women; 20-85 yr., av. age 60), 155 by anterior resection (76 male and 79 female; 32-85 yr., av. age 60), and 53 by abdominoperineal amputation (36 men and 17 women; 35-85 yr., av. age 65). Three were high operations, 38 medium, 98 low and 15 in the anal canal; 10 were imprecisely located. Mortality was 7.9%, 7 men and 6 women; causes of death, emboli, shock, and others. Of those operated upon 115 had uneventful recoveries; complications chiefly due to hemorrhage arose during recovery for 15. Long-term results were local regrowth of cancer occurring in 39 patients (in 4 yr.), and the appearance of metastases in 31 (in 4 yr.), 28 in the liver. Other dysfunctions which may have derived from the operation are discussed. After 5 yr., 50 patients survived the operation. Of those who underwent anterior resection, their lesions were situated more than 10 cm above the anocutaneous margin; there were

42 cancers of the high rectum, 57 of the rectosigmoid and 56 of the lower sigmoid. Mortality was very high (20%; 33 patients) but these operations were done in the clinic and death was often due to advanced stages of cancer or to other severe conditions aggravated by operation. Of the 122 who survived the operation, 15 were alive 5 yr. later. Very few local regrowths of cancer or metastases were reported for this group; 17 cancers in the region of the original lesion and only 13 or 14 metastases. Among the 53 cases of abdominoperineal resection, 8 were rectosigmoid; 38, high ampullary (more than 10 cm); 8, medium ampullary (between 6 and 10 cm); 6, low ampullary (between 3 and 6 cm). Mortality in this group was 40.2% (25 patients; 22 men and 3 women). The causes of death were: 5 emboli, 4 blood ammonia, 8 cardiac failure, 1 delerium, 2 infection, 2 occlusion, 2 hemorrhage, and 1 with repeated perforations. Six were alive 5 yr. after the operation with regrowth occurring in 7 instances in the first yr., and 30 in the second yr.; metastases occurred in about 35% of this group. If possible, the conservative perineal amputation should be chosen.

9304 AN EXPERIMENTAL APPROACH TO ADJUVANT CHEMOTHERAPY IN CARCINOMA OF THE RECTUM AND COLON.

(E.) McKinna, J. A. (Metropolitan Hosp., London E. 8). Proc. Roy. Soc. Med. 60(3): 212-214, 1967.

In 36 in vitro perfusions (oxygenated physiological saline-dextran soln. via Dale-Schuster pump) of arterial system of specimens, it was possible to show release of malignant cells into venous perfusate in 27. Factors involved in release were the presence of a fibrinolytic agent in arterial perfusion fluid and manipulation of tumor and intestinal contraction. In in vivo and in vitro observation, certain areas of rectal and colonic carcinomas were not reached by dyes given arterially. X-Rays of the vascular tree showed a hyperemic zone at the tumor edge and a tendency to avascularity in the center. By addition of human RBC to a perfusion fluid of improved electrolyte composition, in vivo perfusion of 2-3 hr. was possible. In 6 patients, thymidine-^{3}H was inj. intra-arterially within 1 hr. of initiation of the experiment. The label was seen in the crypt cells of normal mucosa, in cells of germinal centers of the lymph nodes, and in the tumor cells. Also ^{35}S-half-sulfur mustard (2-hydroxyethyl-2-chloroethyl ^{35}S sulfide) was admin. (1 mc) through a cannula in the inferior mesenteric vein. The drug also contained Patent Blue Violet to indicate macroscopic distribution. Patchy areas of poor staining were seen in luminal and cut surfaces of tumor. The highest conc. of drug was in the local lymph nodes, in a lethal conc. These results suggest the use of alkylating agents, at the time of operation, to inactivate cells which are released into the circulation at subsequent manipulation and to "sterilize" any malignant cells which may have spread to lymph nodes not excided.

9305 LATE DEVELOPMENT OF COLONIC CARCINOMA COMPLICATING URETEROSIGMOIDOSTOMY.

(E Richter, R. M. (Mount Sinai Hosp., New York, N. Y.) and S. A. Ginsberg. Amer. J. Surg. 113(6):843-845, 1967.

Twenty-two yr. after a bilateral ureterosigmoi ostomy for exstrophy of the bladder and ureter hydronephrosis, completed by cystectomy approx. 1 yr. later, a 24-yr.-old women was presented w a deeply infiltrating adenocarcinoma of the col occurring at the site of the left ureterosigmoidostomy, totally obstructing the retrogra flow of the colon, surrounding and completely obstructing the distal orifice of the left ureter and metastasized to regional lymph nodes Following transverse colostomy and left hemicolectomy en bloc (including the distal 4 cm o the left ureter and the left tube and ovary), intestinal continuity was restored by anastomos of the splenic flexure to the sigmoid and a le cutaneous ureterostomy was created. Postoperative failure of the affected kidney to recover function was followed by nephroureterectomy, at which time extensive, retrograde renal metastases were demonstrated, together with metastatic involvement of the ureter in th area adjacent to the anastomotic junction. The patient died 16 mo. later with metastases to th surgical scars, lungs and liver. In view of th site of the primary neoplasm, it is suggested that the adenocarcinoma may have developed as result of some urinary carcinogen or as a resul of constant irritation of the colonic mucosa, due to the presence of urine, resulting in malignant transformation of adenomatous polyps.

9306 TRITIATED THYMIDINE IN A HISTOAUDIORADIOGRAPHIC STUDY OF ADENOMATOUS POLYPS AND ADENOPAPILLOMA OF THE LARGE INTESTINE WITH PARTICULAR EMPHASIS ON THEIR MORPHOGENESIS AND CARCINOMATOUS EVOLUTION.

(It.) Messinetti, S. (U. Rome), G. P. Zelli, L. R. Marcellino and E. Alcini. Ann. Ital. Chir. 43(2):193-215, 19

Rectoscopic studies were made and numerous bio specimens were obtained from 6 adult patients with hemorrhoids and rectosigmoid cancers; an 18-yr.-old boy with recurrent, disseminated, polypoid rectocolitis following total colectom a 34-yr.-old woman with disseminated rectosigm polyposis and 2 villous polyps and an ulcerati rectosigmoidal adenocarcinoma developing from adenoma; a 28-yr.-old patient with a massive, pedunculated, adenomatous polyp at the rectosigmoid junction. Specimens were incubated wi tritiated thymidine (1 μc/ml) in TC Medium 199 at 37°C for periods of 1, 2, 3, 4, 5 and 8 hr., as were numerous biopsy specimens of normal rectal and sigmoidal tissue and numerous specimens of apparently-normal tissue intervening between adenomatous polypoid formations in the patients with disseminated, polypoid rectocolitis. In such intervening, apparently-norma mucosal tissue, anomalous centers of proliferation were demonstrable, consisting of foci of

enerative activity at or near the apex, rather
n the base, of the Galeazzi-Lieberkühn crypts.
s, in turn, did not appear to be due to
lular migration, but to the presence of ectopic
i of proliferation, created by mechanisms
ch could not be defined. The phenomenon was
ught to represent an initial step in the
phogenesis of adenomatous polyps, since a
ked peripheral dislocation of regenerative
liferation, also at or near the apex of the
pt, was demonstrable in these neoformations but
in normal rectosigmoidal mucosal tissue.
dislocation was also evidenced clearly in
lous polyps. Adenomatous polyps, consisting
either differentiated or undifferentiated
ls, tended to develop eccentrically due to
cessive introflexions of the centers of
liferative activity; while villous polyps,
sisting chiefly of undifferentiated cells,
ded to develop along the line of the papillary
s by means of a succession of extraflexions
these centers of proliferative activity, a
nomenon thought to account for their increased
ential malignancy.

7 A COMPARATIVE ELECTRON MICROSCOPIC STUDY
OF HUMAN AND RAT COLONIC POLYPS AND
CINOMAS. (E.) Spjut, H. J. (Baylor U. Coll.
., Houston, Texas) and M. N. Smith. Exp.
ec. Path. 6(1):11-24, 1967.

onic polyps and carcinomas of white Wistar
s, both sexes, induced by daily s.c. inj. of
'-dimethyl-4-aminodiphenyl (2 mg/100 g), were
died under the electron microscope and com-
ed to similar human lesions. Both showed
nificant alterations of microvilli, desmosomes
nuclei when compared to the normal; however,
ered goblet cells were observed in rat lesions,
not in human neoplasms. Large, dense,
lular inclusions were noted in the rat cecal
osa and polyp, as well as in human polyps and
cinomas. Small, dense, loose groups of intra-
lear bodies were seen in 2 human carcinomas,
their nature was not evident. These electron
roscopic findings represent another area of
ilitude between an experimental model for the
dy of large intestinal neoplasms and the human.

3 STUDIES ON NORMAL AND CECECTOMIZED RATS.
(Ger.) Kunz, E. (U. Basel, Switzerland).
Ernaehrungswiss. 8(1-3):1-27, 1967.

investigate the function of the cecum in
estion, and the effect of the cecum upon
rophagy, cecectomy was performed on young
s (30-40 g). The cecum was ligated and ex-
ed leaving only the ligated stump which was
ured by 3 Lembert cross-ties. Histological
mination of the cecal stump, from animals up
2 yr. after operation, showed no tendency of
thelial overgrowth and no inflammation in
um or large intestine; the serosa remained in
ellent condition. An aftereffect was the
ardation of body growth which was less
strongly expressed in sham-operated animals. The operated rats were fully viable and with normal feeding never showed any digestive disorders in 2 yr. of observation. Paired animals, 1 operated and 1 normal, in a special battery of cages, were studied for metabolic processes; daily determinations of water, food consumption, urinary and fecal output, and measurement of body wt. were carried out. Coprophagy was controlled. These methods allowed the testing of different diets such as, a normal formulated complete nutrition, a protein-poor diet, or a single type of food as barley, or rolled oats, on cecectomized and normal rats. Cecectomized rats had a travel time through the alimentary tract of 4.5-7.5 hr. (normal diet). The normal rat had a greater variation of 4.5-36 hr. due to possible cecal storage. In normal animals about 35% of the food did not pass through the cecum (filled) and moved from ileum into the large intestine. Food material may remain in the cecum up to 30 hr.; the most frequent time intervals were 2-10 hr. (26%) and 18-30 hr. (29%). The cecum never emptied completely. Cecectomized rats were coprophagic resulting in better food utilization and an increased food intake. Cecectomy without coprophagy caused an inefficient utilization of food. If fed a complete diet, rats deprived of their cecum show growth depression due to lower food utilization. Protein deficiency or a uniform diet cause a diminished utilization which is compensated by more food intake. The net result is a growth rate comparable to a normal rat growth rate. Graphs show that the growth rate of normal animals is depressed on a protein-deficient or a uniform diet to conform to that of the cecectomized animals on the same diet.

THE ANTI-COLON ANTIBODIES DURING HEMORRHAGIC RECTOCOLITIS. (Fr.)
, P. (Med. Clin. "B", Nantes, France),
eibaum, G. Terris and B. Halpern. Path.
(Paris) 15(7-8):345-348, 1967.

rch for antibodies against the human colon
nvestigated using immune fluorescent technic
cases of ulcerative colitis and 250 controls.
were obtained from the 44 patients and from
50 controls as were biopsy specimens of
ic and rectal mucosa; the activity of some
upon biopsies of the fundus and ileum was
studied. Fluorescent immune sera (anti-
γ-globulin fluorescent γ-globulins) were
oped in the rabbit and prepared by Goldstein's
ic. The frozen sections were examined by
ndirect immunofluorescent method. The
tivity of the method was checked against
e sera developed in the goat. The specificity
e reaction was confirmed by Coons' test.
odies could be demonstrated in colon samples
patients, but the serum of only 1 patient
ed with all the samples of human colon
ed. The apparent discrepancies in the
ature of the subject are probably due to
ariability of the antigenic composition of
uman colon. Colonic material of dog, rat,
onkey reacted only with the anti-A agglutinins
e sera of the 44 patients and the 250 con-
, i.e., in the sera of 13 patients and 81
ols.

TOXIC MEGACOLON. SIGNIFICANT IMPROVEMENT IN SURGICAL MANAGEMENT. (E.)
ec, N. A. (Mayo Clin., Rochester, Minn.),
Judd and W. G. Sauer. Arch. Surg. (Chicago)
:638-643, 1967.

al of 37 patients with toxic megacolon are
ted; they were divided into 2 groups, medical
atients) and surgical (23 patients), depend-
pon the ultimate form of treatment given.
ccurrence of toxic megacolon often appeared
related to diagnostic investigative proce-
and therapeutic regimens; 57% of the medical
and 35% of the surgical group had Ba enemas
. of 8.6 days (range 1-23) before onset of
megacolon; in 43% of the 37 patients, toxic
ation developed within 9 days of Ba enema
. One patient in the medical group and 4
in the surgical group developed toxic
olon 2-6 days after admin. of codeine.
al treatment consisted of admin. of antibi-
and chemotherapeutic agents to all patients,
ll as vigorous replacement therapy. Improve-
occurred in the 14 medically treated patients,
e av., within 7 days; duration of hospitaliza-
av. 31.2 days (range 11-60). One medically-
ed patient died, but death was not related
tly to toxic dilatation of the colon. The
rgically-treated patients were hospitalized
. of 19 days before surgery; the av. for
ntire hospitalization was 50.5 days. Nine of the 23 had perforations of the colon, and in 5 they were multiple; in 3 of the 9, perforations were diagnosed preoperatively. Indications for operation were 1) persistent dilatation, bloody diarrhea and failure to improve in 12 patients; 2) persistent dilatation and failure to improve in 7; 3) colonic perforation in 3; and 4) obtunded state on admission with no improvement on medical treatment in 1. The surgical procedures and number of cases were as follows: total proctocolectomy, 3; subtotal colectomy and ileostomy with mucous fistula or Hartmann procedure, 10; subtotal colectomy and ileostomy with subsequent abdominoperineal resection, 7; subtotal colectomy and ileorectosigmoidostomy, 1; and ileostomy and ileomucous fistula, 2. Eighteen complications occurred in 13 patients; wound infection was found in 6, wound dehiscence in 1 who was on steroid therapy, and 1 each of the following occurred: abscess at the ileostomy site, staphylococcal enteritis, persistent ileus, fecal abscess secondary to perforation of splenic flexure, jaundice (which cleared spontaneously), pulmonary embolism, and right pleural effusion (which cleared spontaneously). Three surgical patients died. One death was due to an abscess about the rectal stump and associated peritonitis, 1 was due to empyema of the right pleural space, bacterial endocarditis and peritonitis and the third to peritonitis. The mortality was 13% for the surgical patients, and 11% for the entire series.

9366 PROCTITIS (RECTO-SIGMOIDITIS, INFREQUENT RECTOCOLITIS HEMORRHAGICAL) IN THE AMBULANT GASTROENTEROLOGIC PRACTICE OF A LARGE CITY. THIRTY-SEVEN CASES AMONG 10,000 NEW PATIENTS. (Ger.) Kaufmann, W. (Wallrafplatz 1, Cologne, Germany). Gastroenterologia (Basel) 107(3):161-163, 1967.

Hemorrhagic rectocolitis is essentially ulcerous, usually acute or subacute, and fairly difficult to treat. The incidence is greatest in the rectum and sigmoid so that the proctoscope is the chief diagnostic tool up to the upper end of the sigmoid loop. Of 10,000 cases, 37 (13 men and 24 women) had this condition or its variants, while 60 patients, mostly elderly, were discovered with cancer of the rectum or sigmoid. Most of those with rectocolitis were 30-50 yr. old; 1 man and 4 women were less than 30 yr. old. Among the young there was a tendency toward urticaria, eczema and psychoneurotic manifestations. Sometimes a change of environment proved beneficial, therefore, the usual therapy with high doses of salazosulphapyridine (Azulfidine), phanquinon (Mexaform) and prednisone did not seem warranted. Two of the 37 patients did poorly; 1 developed swelling of the descending colon with narrowing of the lumen, and was sent to surgery (the only 1 of the 37); 3 days after colectomy the patient was dead of pulmonary emboli. The other case, (a 32-yr.-old man) after

6 wk. treatment with improvement, received intensive treatment for 3 mo. with daily 6 tablets of salazosulphapyridine as well as 6 phanquinon in addition to 19-nortestosterone 17-phenylpropionate (Durabolin), streptomycin 25 mg prednisone, and desoxycortone (Decortin), together with a special diet. After 3 mo. the patient had lost 11 kg more and had developed a bleeding peptic ulcer. He was transferred to surgery and 3 wk. later underwent rectocolonic amputation. A few days later a massive hemorrhage occurred from the peptic ulcer and the patient died. Lighter medication and a milder diet are recommended.

FUNCTIONAL CLINICAL DIAGNOSTIC TESTS
FOR CARCINOMA OF THE PANCREAS. (WITH
AL REFERENCE TO THE PANCREOZYMIN-SECRETIN
AND PROTEOLYTIC ACTIVITY OF THE STOOL.)
) Filippini, L. (U. Zurich, Switzerland) and
mann. Schweiz. Med. Wschr. 97(25):803-810,

hymotrypsin and trypsin activity of the stool
letermined in 21 patients with malignant, but
ndocrinically active, pancreatic tumors (19
of cancer of the head and 2 cases of the body
e tail of the pancreas). In addition, the
eozymin-secretin test could be carried out
cases. Trypsin and chymotrypsin activities
done with synthetic specific substrates.
nal juice was analyzed for chymotrypsin,
in and also amylase after admin. of pancreo-
and/or secretin. The most reliable parameter
ncer of the head of the pancreas proved to be
ntraduodenal enzyme output following pancreo-
: The values for diastase (U), trypsin (γ),
hymotrypsin (γ), (20 min. secretion) were,
, 4105, 1374, 791, (normal values, in the
order, 32,200, 13,200, 10,500). This was the
or 16 patients, but 3 others with cancer of
ead of the pancreas as well as 2 with
r of the body or tail had values approx. 3
normal for the same time interval. Sixteen
patients showed depressed fecal chymotrypsin
s, the fecal trypsin values were less reliable.
suggested that fecal chymotrypsin be used as
eening test inasmuch as it correlated well
the pancreozymin-induced secretion of
trypsin in the duodenum.

SYSTOLIC MURMUR OF THE SPLENIC ARTERY,
A SIGN OF CANCER IN THE BODY OF THE
EAS. (Fr.) Warter, J. (Fac. Med., Strasbourg,
e), J. Schwarts, A. Sacrez and B. Gillet.
bourg Med. 18(3):281-287, 1967.

cases a systolic murmur was heard by auscul-
n of the left subumbilical region and the
hypochondrium due to compression of 1 or more
ies near the pancreas and, principally, com-
ion of the pancreatic artery itself. Ab-
al arterial phanangiograph showed a type of
r caused by narrowing of the arterial lumen.
esults of an aortograph or selective arteriog-
of the celiac trunk should logically prove
contentions; locating the condition precisely
isclosing the mechanism. The fifth case, a
.-old woman with abdominal pain had recently
gone a severe change in her general condi-
she had hypertension not noted in her 2-yr.-
ecords; she complained of epigastric pain
ting to the left hypochondrium and resistant
l treatment, beginning 14 mo. before; begin-
12 mo. before she lost wt. rapidly, accom-
d by some vomiting. Abdominal examination
ot reveal a tumor; the remainder of the
examination revealed an arterial blood pressure of 200/110 and a left hemiparesis with a left Babinski sign. Bilirubin was high, 21 mg%; WBC count was high (11,000/mm^3); RBC was low, 3,400,000/cu mm; hemoglobin was low, 62%. All other tests were normal including gastroduodenal transit. Urography i.v. was negative. Auscultation of the left epigastrium and hypochondrium revealed a typical systolic murmur. Selective arteriography of the celiac trunk indicated that part of the arterial narrowing was splenic and hepatic with stenosis of the median branch of the splenic artery. Diagnosis of cancer of the body of the pancreas was confirmed at surgery, but hepatic and peritoneal metastases rendered pancreatectomy impossible. The arterial murmur was recorded together with the electrocardiogram and the arterial pulse; the murmur possessed a very large high frequency component.

9375 RENAL DAMAGE IN ACUTE DISEASES OF THE PANCREAS. (Ger.) Dabels, J. (U. Clin. Rostock, Germany), K. Diwok and M. Gülzow. Deutsch. Z. Verdau. Stoffwechselkr. 26(5-6):229-241, 1966.

Among 267 patients, 101 with necrosis of the pancreas and 166 with moderately severe pancreatitis, 72 died (only 3 with pancreatitis). From clinical evidence (uremia) and from autopsy it was clear that 16 of these patients succumbed to renal failure. Of the 69 with pancreatic necrosis, 38 had some degree of renal damage visible at autopsy. The symptomatology of kidney damage following pancreatic disease was striking: in 236 patients with pancreatic necrosis and pancreatitis 50.8% or 120 had proteinuria and 29.2% or 69 had erythrocyturia early in the pancreatic disorder. Those with pancreatic necrosis had a higher percentage of pathological urinary findings than those with moderately severe pancreatitis. Nonprotein nitrogen excretion was increased 53% in 74 with necrosis and 25% in 86 with pancreatitis. The xanthoprotein reaction fell in 23% of those with necrosis and in 17% of the cases of pancreatitis. In most of the patients the endogenous creatinine clearance was decreased in the acute stage of pancreatitis and the plasma levels of creatinine increased. The severity of the renal disturbances ran parallel to the pancreatic malfunctions. Electrolyte imbalances, especially of Ca, and water loss resulting in oliguria, appeared toward the end; renal blood flow decreased. Water loss occurred through earlier excessive urination, vomiting, accumulation of fluid in the peritoneal cavity. Proteinuria caused a drop in the oncotic pressure of blood plasma with loss of water into tissue spaces. Possible etiologic factors were 1) Shock causing renal ischemia, 2) toxic activity of breakdown products of protein, 3) damage caused by proteolytic enzymes of the pancreas, 4) intravascular coagulation.

9376 PANCREATIC ISCHEMIA TOLERANCE. (Ger.) Moser, R. (Surg. U. Clin. A, Zurich), H. U. Meili and F. Largiadèr. *Z. Ges. Exp. Med.* 143(3-4):266-276, 1967.

A group of 28 dogs (18-27 kg) were laparotomized under anesthesia with artificial respiration, the gastro- and pancreaticoduodenal arteries, and the pancreatic branches of the linealis artery were laid bare and looped with ligature thread; small blood vessels in the mesoduodenum and the posterior fold of the greater omentum were electrically coagulated. Finally, the animals were heparinized and the arteries named clamped off with bulldog clamps. To hinder any blood flow to the pancreas over duodenal pathways the pylorus and the lower third of the duodenum were lightly clamped off. The completeness of the pancreatic ischemia was tested by the i.v. inj. of the vital dye Citon Fast Green in 10% soln. The duration of the ischemia was from 1-6 hr.; the abdomen was temporarily closed by clips. The pancreata with 6 hr. ischemia were cooled to 7°C, with a thermostatically-controlled cooling system operating through a balloon. In some cases the electrocardiogram and the blood pressure were registered; blood vol. was measured by ^{131}I-radioactivity. Pancreatic tissues obtained from these animals were prepared for optical and electron microscopy. Ischemia of the pancreas up to 4 hr. was tolerated with month-long or greater survival. Ischemia of 5-6 hr. resulted in a survival time of only 1 day in 8 of 15 dogs. The others survived from 4 days to more than 2 mo. (2 dogs). A rise in serum amylase was often observed but there was no apparent correlation with the duration of ischemia. Electron microscopy showed pronounced intracellular damage even with ischemia of only 2 hr. This consisted of chromatin clumping in the nuclei with marked folding and wrinkling of the nuclear membrane, swelling of mitochondria and a translucence of zymogen granules. The matrix space became lighter. The protein secretion of the exocrine cells was conc. in the canals of the Golgi apparatus in the apical region of the cells as thick zymogen granules. After the ischemia these large zymogen granules disappeared. No differences were visible in the conventional histologic preparations of the surviving animals at the end of ischemia. Histological evidence of damage was always present in autopsy material.

9377 MODIFIED TECHNIC FOR THE ISOTOPIC TRANSPLANTATION OF THE PANCREAS. (Ger.) Largiadèr, F. (Surg. U. Clin. A, Zurich). *Z. Ges. Exp. Med.* 143(3-4):261-266, 1967.

Dogs served as donors (16.5-39 kg) and as hosts (19.5-33 kg). Fundamentals of the surgical technic included: 1) In the donor the entire pancreas and duodenum were removed together with the celiac trunk and its branches and the portal vein with its tributaries. A duodenopancreatectomy with an end-to-end cholecystoduodenostomy was performed in the host. The celiac trunk of the transplant with a cuff formed of the donor aortic wall was implanted in the subrenal abdominal
aorta, and the portal vein in the suprarenal
cava of the host; the proximal duodenum of th
transplant was joined end-to-end with the sto
and the distal duodenum with the small intest
of the host end-to-side. Variations in the s
gical technics were confined to different ana
tomoses of the blood vessels. To allow for a
physiologic passage of pancreatic venous bloo
through the liver, the portal vein of the tra
plant was implanted into the distal portal ve
of the host instead of into the inferior vena
cava. Some complications encountered in earl
trials can be avoided: 1) Implanting the stu
of the common bile duct in the duodenum inste
of ligating it prevented necrosis of the stum
and insufficiency. 2) Ascending cholangitis
prevented by implanting the graft at a lower
i.e., in the second loop of the jejunum. 3)
ulcerative duodenitis seen in animals survivi
for longer periods was reduced by gastric res
tion in the host. If the inferior pancreatic
duodenal artery was retained on the transplan
amputation of the unicate process of the panc
was unnecessary. This was based upon the experience gained in 51 transplantations with s
vival times of the recipient up 49 days.

9378 SALIVARY STUDIES IN CYSTIC FIBROSIS
(E.) Mandel, I. D. (Columbia U. Sc
Den. & Oral Surg., New York City), A. Kutsche
C. R. Denning, R. H. Thompson, Jr. and E. V.
Zegarelli. *Amer. J. Dis. Child.* 113(4):431-4
1967.

Parotid and submaxillary saliva were obtained
from 62 subjects (28 male, 34 female; 6-19 yr
old; 75% were 9-13 yr. old) with cystic fibro
and a group of apparently healthy individuals
similar in age and sex who served as controls
Amylase, lysozyme, urea and uric acid were assayed in parotid saliva; 2 amylase methods we
used: the Caraway modification of the standa
Smith-Roe starch-iodine (amyloclastic activit
and 2) the Berenfeld dinitrosalicylic acid-reducing sugar method (saccharogenic activity).
Although mean and median values of amylase we
higher in cystic fibrosis patients, there wer
significant differences between the groups wi
either of the 2 procedures. The mean and
median values for lysozyme activity were lowe
for the cystic fibrosis group, but difference
were not significant. Ammonia levels and flo
rate were almost identical in the 2 groups, b
urea nitrogen and uric acid were significantl
higher in the cystic fibrosis group. In the
study of submaxillary saliva, the cystic fibr
group had statistically significant elevation
Na, Cl, Ca, P, urea and uric acid; K values w
not significantly higher, and flow rate was l
in the cystic fibrosis group. Values for tot
protein, fucose and hexose were significantly
higher in cystic fibrosis patients. With the
dinitrosalicylic acid procedure, cystic fibro
patients exhibited a significantly higher amy
activity than controls; the elevation was not

ounced with the starch-iodine method. Lysozyme
ity was significantly higher in the cystic
sis group. Polyacrylamide gel disc electro-
esis was used as a means of comparing the
rn of submaxillary protein fractions from
nts with mucoviscidosis with a control group
ildren; when equal vol. of submaxillary saliva
compared, the cystic fibrosis group exhibited
intense staining and a greater number of pro-
discs than controls; when the vol. were ad-
d so that equal amounts of protein were com-
, the major difference between the 2 groups
somewhat greater intensity of staining in
'amylase-glycoprotein region" in the gels with
c fibrosis samples. The other areas were
comparable in number and intensity of discs.
ntrast to rather limited alteration in over-
omposition observed in the parotid secretion,
xillary saliva was markedly altered in cystic
sis patients. Based on comparison of mean
s with healthy controls, cystic fibrosis pa-
s had significant elevations in 1) electrolytes
, Cl, Ca and P; 2) the organic nonelectrolytes,
and uric acid; and 3) total protein, amylase,
yme and protein-bound hexose and fucose.
stically, the most significant elevations in
c fibrosis patients were in conc. of Ca and P.

THE PHYSIOPATHOLOGY OF THE EXOCRINE
FUNCTION OF THE PANCREAS BEFORE AND
BILLROTH II. (Ger.) Wagner, E. (U. Giessen,
ny). Deutsch. Med. Wschr. 92(22):1016-1022,

xocrine function of the pancreas was measured
tients before and after gastric resection
onstruction of Billroth II and compared to
ancreatic function of normal healthy in-
uals. The standard methods of Rick were used
specific stimulation of the gland by means
cretin and pancreozymin. The duodenal and
ic secretions were separately collected by
ble-balloon 3-way catheter in the preoperative
ormal subjects. For the collection of duo-
fluid from the afferent loop of Billroth II,
ble-balloon 2-way catheter especially de-
d for the purpose was used; this was also
for the recovery of secretion from the gas-
stump. The dose of secretin and pancreozymin
clinical U/kg body wt. i.v. The vol. of
tion, bicarbonate conc. and the rate of
tion of trypsin, chymotrypsin, carboxypep-
e A, amylase and lipase were determined.
a betazole inj. the acidity of the gastric
, collected over a period of 2 hr., was
ted. A total of 107 pancreas function tests
completed. Test runs on 20 ulcer patients and
rmal subjects showed that these 2 groups had
the same rate of enzyme secretion in the
nal fluid. Nine of the 20, however, had a
ased bicarbonate conc. Vol. of secretion
he same; 4 mo. after a Billroth II in 10 of
ses there was evidence of secretory dis-
nce of the pancreas best described as a
tory stasis. At least 4 yr. after operation
59 patients investigated showed either some
degree of dissociation of enzyme secretion or a total loss of secretion; 16 patients had subnormal secretion vol. and 26 had bicarbonate conc. below normal. The action of secretin and pancreozymin reveals the limitation of pancreatic secretion some time after the operation resulting from increased atrophy and, finally, fibrosis of the gland. Fibrotic transformation of the gland has been observed, increasing with time following a Billroth II. The afferent loop should be as short as possible.

9380 STIMULATION OF INSULIN SECRETION BY SECRETIN IN MAN. (Ger.) Bottermann, P. (U. Munich, Germany), K. Schwarz, M. M. Forell, H. Stahlheber and A. Souvatzoglou. Klin. Wschr. 45(1):52-53, 1967.

After a number of preliminary trials, it was discovered that the simultaneous i.v. inj. of glucose (0.5 g/kg body wt. as a 50% soln.) and secretin (1.5 U/kg body wt.) raised the blood insulin level significantly above the increase caused by the admin. of glucose alone. Thus the av. increase of serum insulin was 140 μU/ml in 6 subjects (from 40 to 180 μU/ml) in 10 min. inj. with glucose only; for the same 6 subjects under the same experimental conditions inj. simultaneously with glucose and secretin, the av. rise in serum insulin was 263 μU/ml (from 40 to 303 μU/ml) in 10 min. The peak insulin conc. in both groups of tests came at 10 min. after inj. The decline in serum insulin was less rapid when glucose only was inj.: After 1 hr. the serum insulin level was 130 μU/ml. One hr. after inj. of both glucose and secretin the serum insulin level was 100 μU/ml. The fall in each case was nearly linear. The admin. of secretin alone was without any effect upon the serum level of insulin. The β-cytotropic effect occurs in man.

9381 CHRONIC DIARRHEAS IN INFANCY AND CHILDHOOD. II: ENZYME CONTENT OF DUODENAL JUICE. (E.) Ingomar, C. J. (Dronning Louise Child. Hosp., Copenhagen) and E. Terslev. Arch. Dis. Child. 42(223):289-293, 1967.

The study was done on 112 children up to the age of 6; 42 were normal controls; 70 had diarrhea and were suspected of malabsorption or maldigestion. Excluded were cases of diarrhea due to dietary errors, cases of intestinal infection or cases due to parenteral infections; the conditions had been of relatively long-standing. Activities of amylase, lipase, and trypsin of the duodenal fluid were collected by aspiration, unmixed with gastric juice, for 1 hr. after stimulation by powdered buttermilk (Eledon); the position of the duodenal tube was checked radiologically; during its collection the duodenal fluid was cooled on ice and immediately after collection it was frozen at -16°C. The following tests were also applied to each patient: 1) determination of fecal fat on a diet with a known fat content, 2) D-xylose tolerance test, 3) determination of

Na and K in perspiration. On the basis of these 3 tests the 70 patients were divided into 4 groups: Group 1 (8 cases) sweat test abnormal, Na excretion greater than 6 mEq/liter and Na:K ratio greater than 2:5. Group 2 (22 cases) sweat test normal but D-xylose tolerance test abnormal, max. xylose conc. in blood less than 26 mg/100 ml after admin. of 15 g D-xylose/m^2 body surface area, and excretion in 24-hr. urine less than 16% of admin. quantity. Group 3 (16 cases) sweat tests and D-xylose tolerance normal but fecal fat equal to or greater than 10%. Group 4 (24 cases), all 3 tests normal. The amylase activity in the fasting duodenal juice from infants under 6 mo. of age was low; lipase activity was lower in infants and children under 2 yr. than in children over 2 yr. A consistently low enzyme activity (amylase, lipase and trypsin) was found only in patients with mucoviscodosis, i.e., Group 1. Group 4 children with normal sweat, fat excretion, and D-xylose tolerance tests had enzyme values no lower than the control group. Infants and children, Group 2, with normal sweat tests but abnormally low D-xylose tolerance tests did not show any reduction in pancreatic enzyme activity. Group 3 individuals with normal sweat tests and normal D-xylose tolerances but increased fecal fat showed moderately low values for some enzymes, suggesting pancreatic insufficiency.

9407 FEEDING BY JEJUNOSTOMY IN THE TREATMENT OF ACUTE SEVERE PANCREATITIS. (Fr.) Kiekens, R. (Brugmann Hosp., Brussels), P. Kinnaert and J. P. Govaerts. Acta Chir. Belg. 66(1):45-57, 1967.

Two cases are reported in detail of the feeding by jejunostomy following the acute phase of necrotic hemorrhagic pancreatitis; these patients were affected by a prolonged gastric inability to tolerate feeding. Feeding by jejunostomy prevented profound nutritional defiency in spite of long and difficult postoperative courses. Both patients were admitted with violent epigastric pain, elevated serum and urinary amylase, high WBC counts; 1 had a serum Ca level of only 6 mg%. Both underwent partial pancreatectomy and the construction of a jejunostomy about 20 cm below the angle of Treitz. Upon return of peristalsis water was introduced through the jejunostomy, then progressively larger amounts of nutritional fluids. In 1 case feeding was exclusively by jejunostomy for 1 mo., then gradually over a period of 3 wk. and feeding was reinstituted; the jejunostomy tube was removed 2 mo. after the operation. In the other case, feeding through jejunostomy was continued for 3 wk. At the end of the first wk. of jejunostomy feeding the patient tolerated 2 liters of homogenized foodstuffs and sugar water. The homogenized foodstuffs contained casein, dried milk, potatoes and legumes with a supplement of NaCl; this preparation had 1000 calories/liters. At first, the digestion and absorption of foodstuffs was inadequate, especially fat which was kept low in the homogenate. Gradually over the period of observation the enzyme conc. of trypsin, amylase and lipase rose to about half the normal values. The patients had received blood and blood plasma during and after surgery in the usual amounts. One patient maintained his wt.; the other lost 3.5 kg. Feeding by jejunostomy in this type of case seems to have definite advantages.

9408 CHOLEDOCHODUODENOSTOMY IN TREATMENT OF CHRONIC PANCREATITIS AND CHOLEDOCHOLITHIASIS. (E.) Burgess, J. N. (Mayo Clin., Rochester, Minn.) and H. A. Kidd. Brit. Med. J. 2(5552):607-609, 1967.

Over a 10-yr. period 31 patients were treated by choledochoduodenostomy for chronic pancreatitis and/or choledocholithiasis; 27 were followed-up by personal interview; 3 others, over 85 yr. of age, were seen by their own physicians. All were asked if the results of the operation were satisfactory, if they had since suffered abdominal pain or indigestion, become jaundiced, lost wt., or had experienced diarrhea; they were asked about bowel movement and appetite and if they had experienced pain on taking fizzy drinks. At the time of operation ages varied from 34-86 yr. with an av. of 62 yr. The follow-up occurred from 1 mo.-10 yr. after surgery and av. 4 yr. A the operation a thorough exploration was made of the biliary tract and the pancreas. Cholecystectomy was performed, if necessary, and a side-to-side anastomosis made between the bile duct and the duodenum. No operative deaths occurred. Of 22 undergoing this operation for chronic pancreatitis, the results were good in 20 patients (91%); 10 patients had no symptoms whatsoever; 5 had occasional slight epigastric discomfort after meals; 2 had occasional mild heartburn; 3 felt brief right hypochondrial pain after drinking fizzy water only, possibly due to passage of gas into the bile duct. Two cases showed poor results; 1 a 66-yr.-old diabetic female suffered from lower abdominal colic with diarrhea and jaundice; the other, a 34-yr.-old woman suffered repeated attacks of epigastric pain radiating through to the back. Nine patients with choledocholithiasis were operated upon. Four had previous cholecystectomy and exploration of the common bile duct; the other 5 had multiple stones in the common duct; 2 patients died of congestive heart failure 9 and 20 mo. after surgery; 8 of the 9 patients had good results; a 71-yr.-old woman suffered abdominal pain relieved by simple laparotomy; no abnormality was found. Choledochoduodenostomy by side-to-side anastomosis is the treatment of choice for chronic relapsing pancreatitis and choledocholithiasis.

9409 MARGINAL NEUROTOMY IN SOME FORMS OF CHRONIC PANCREATITIS. (Rus.) Trunin, M. A. (Leningrad Sanit.-Hyg. Med. Inst., USSR) and I. F. Krutikova. Vestn. Khir. Grekov. 98(1): 47-53, 1967.

A new surgical procedure on the autonomic nervous system in severely painful chronic pancreatitis is presented, based on the results of studies of the innervation of the pancreas (on 45 human adult cadavers and 25 animals, probably dogs), data from the literature, experimental material and clinical observations. Marginal neurotomy consists of max. complete resection of autonomic nerves approaching the pancreas on its perimeter. The procedure is as follows: Lateral or upper central resection of the abdominal cavity is followed by opening of the bursa omentalis through the gastrocolic ligament and revision of the ligament and pancreas; parietal peritoneum was opened along the upper end of the pancreas, novocain was admin. under the semilunar ganglions of the solar ganglion located to the right and left from the celiac stem, and nerves approaching the pancreas from right and left were resected; additionally, peritoneum above the mesenteric vessels was incised and the pancreas was mobilized with resection of the approaching nerves. It is desirable to incise the lower pancreatic-duodenal artery in order to destroy its autonomic plexus bringing nerves to the pancreatic head.

necking of hemostasis, drainage of the bursa nentalis and suture of the wound in layers ollowed. The advantages of this suggested rocedure include decreased trauma, disturbance nly of the innervation of the pancreas, a reuced incidence of postsurgical complications, nd achievement of good results not only in the ase of an isolated involvement of the head but so in total involvement of the pancreas. arginal neurectomy was performed on 18 patients men, 15 women; 26-61 yr. old) with severely ainful chronic pancreatitis. Preliminary reults (with a follow-up of more than 10 mo.) are ncouraging. Two case histories are given in etail.

410 INTERRELATION BETWEEN CHRONIC PANCREATITIS AND MYOCARDIAL LESION. (Rus.) aramonova, E. G. (Nutr. Inst., Acad. Med. Sci. SSR, Moscow) and S. A. Tuzhilin. *Sovet. Med.*)(12):67-72, 1966.

ased upon 3 patients (women, 36-54 yr. old), it as found that in patients with chronic panreatitis the content of pancreatic trypsin participating in coagulation and anticoagulant ctivity) was increased. It is probable that oronary changes (as observed on the electroardiogram) are not purely reflex in nature, as ome authors believe, but also are biochemical in ature. Coronary changes are evidently nditioned by a disturbance in cardiac muscle etabolism and this is easily reversible with nticoagulant therapy. These changes are quite ossibly related to disturbances in electrolyte etabolism, especially K, which are often oberved in acute and chronic pancreatitis. Changes the psyche are also found, since disturbances the blood supply due to increased coagulation chronic pancreatitis involve both heart, uscle and brain tissue. An inverse relationship etween cardiac and pancreatic symptoms was ound, possibly conditioned by a disturbance of ne physiological balance among the enzymatic ystems. In addition, the hypothesis that a high rotein diet stimulates blood coagulation was erified. Thus, a high-protein diet is contrandicated in patients with chronic pancreatitis ho have increased coagulation activity, especially the presence of cardiovascular diseases. In uch cases, a high-protein diet should also nclude heparin.

411 PHOSPHOLIPASE A-A POSSIBLE DIFFERENTIATING FACTOR IN THE PATHOGENESIS OF ACUTE ANCREATITIS. (Ger.) Schmidt, H. (U. Clin. ottingen, Germany), W. Creutzfeldt and E. abermann. *Klin. Wschr.* 45(3):163-164, 1967.

rouped rats (200 g) were each inj. in the ancreatic duct with 0.6 ml of 1 of a number of reparations, all in Ringer's soln.: (1) ysolecithin, 0.2%; (2) lysolecithin, 2.0%; (3) hospholipase A from bee venom, 250 μg/0.6 ml; (4) a taurocholate, 0.4%; (5) phospholipase, 250 g/0.6 ml and Na taurocholate, 0.4%. Normal human pancreatic juice and bile mixture was obtained. Histologic preparations were made from the necrotic and apparently normal regions of the pancreas of a patient dead from acute pancreatitis. Normal human pancreatic tissue was also prepared from a healthy pancreas. The spontaneous proteolytic activity in freshly-prepared tissue homogenates was measured. Lipid extractions were made and lipid fractions quantitatively determined by appropriate methods including thin-layer chromatography. Inj. of 2% lysolecithin produced complete necrosis of the pancreas within 6 hr.; in addition, necrosis was evident in the adipose tissue of the peritoneal cavity. Despite massive necrosis the proteolytic activity was very small. Even inj. of 0.2% lysolecithin caused necrosis clearly demonstrable in histologic section. Inj. of phospholipase A alone caused no evident necrosis. Inj. of phospholipase A together with 0.4% Na taurocholate (which had very little necrotizing activity) caused the severest degree of necrosis within 1 hr. and also necrosis of adipose tissue in the peritoneal cavity. Analysis of necrotic pancreatic tissue showed the increase of lysolecithin and lysocephalin at the expense of the normal lecithin and cephalin fractions. In the necrotic pancreatic tissue of the rat, expressed as % of the phospholipids, lysolecithin was 45.3, normal, 1.6; lecithin was 19.3, normal 53.1; cephalin 7.9, normal 25.4. The human bile and pancreatic juice mixture incubated for 2 hr. at 37°C had a quantitative conversion of lecithin into lysolecithin. Normal human pancreatic tissue had only 0.3% of the extracted phospholipid in the form of lysolecithin. The necrotic pancreatic tissue of the acute pancreatitis case had 46.2% as lysolecithin, with concomitant fall in lecithin and cephalin. The non-necrotic region of the pancreas had a lysolecithin of 9.3% probably increased by autolysis, and lecithin of 43.8%.

9412 PANCREATIC REACTION DURING OPERATIONS ON THE BILE DUCTS. (Fr.) Pstruzina, J. (Charles U., Prague). *Lyon Chir.* 63(2):194-198, 1967.

Serum lipase levels were measured in McDonald U (pathologic above 0.80) during operations on the biliary routes. Altogether 68 patients were operated upon; 33 cholecystectomies, 12 of which were done without prior ligature of the bladder; 14 with ligatures, and 7 with blockage of the bladder; serum lipase rose from 0.2 to 0.5 U in the first group and remained less than 0.3 U in the other 2 groups. Among 6 who underwent transduodenal sphincterotomy, the serum lipase levels rose to over 1.00; in 4 others with this operation, protected by 30,000 Kallikrein I.U. of Trasylol and 1 g chlortetracyline, the serum lipase reached the same level but diminished more rapidly. In 25 patients who had radiomanometry, measurement of bile output and exploration of the ducts the serum lipase conc. rose to a max. of 0.45 U. In 10 nonoperated subjects and in 10 nephrectomized patients lipase values remained between 0.2 and 0.3 U. In 10 cases of Billroth I resections lipase rose rather slowly to a level of 0.48 U. The blood samples for these tests were taken hourly from the beginning of the operation. The estimation of pancreatic enzyme during surgery can aid in the early diagnosis of postoperative pancreatitis.

9413 THE SIGNIFICANCE OF "POLYMACULAR" PICTURES OF WIRSUNG'S DUCT. AN EXPERIMENTAL ANALYSIS. (Fr.) Mallet-Guy, P. (Edouard Herriot Hosp., Lyon, France), J. Féroldi, J. Murat, A. Ray and F. Abbound. Lyon Chir. 63(2):185-193, 1967.

Duodenotomy and transpapillary catheterization were done in 23 dogs, after which the entire terminal part of the pancreatic duct was cleared by dissection, incised and intubated in order to aspirate its contents and inj. into the duct under controlled pressure a fluid fulfilling 3 objectives: (1) the correct opacification of the excretory tree, (2) visual recognition of fluid diffused into the surface of the gland, (3) deposition of material in histologic sections. Such a preparation was found in 4% Chicago blue holding in suspension a small quantity of BaSO4 as an indicator of rupture when viewed under the microscope. The inj. of an isotonic saline soln. into the pancreatic duct produced edematous lesions with hyperamylasemia when the pressure reached 30 cm of H_2O. For inj. of the Chicago blue preparation a pressure of 35 cm of H2O was used except in 1 case in which the pressure was 80 cm H_2O. Immediate proof of rupture was furnished by the blue patches which appeared at the surface of the gland because Chicago blue does not diffuse through tissues (as does patent blue). In the instance where the inj. pressure was 80 cm of H_2O, the dye was diffused throughout the gland. In 25% of the cases the graphic representation of the pancreatic duct was normal; in 18 animals the picture of characteristic spotting occurred. In graphic representations of pancreatic duct ruptures do actually occur at a pressure of 35 cm of H_2O and have no clinical significance in diagnosis of chronic pancreatitis. In fact, radiography of the pancreatic duct may cause fatal pancreatitis.

9414 ESSENTIAL HYPERLIPEMIA AND ACUTE PANCREATITIS. (Ger.) Braunsteiner, H. (Med. U., Innsbruck, Austria), M. Herbst, S. Sailer and F. Sandhofer. Schweiz. Med. Wschr. 97(22):698-702, 1967.

The relationship of hyperlipemia and some form of pancreatitis has been obscure although cases are on record of the occurrence of episodes of pancreatitis in hyperlipemic individuals. Essential hyperlypemia has been observed in 36 cases in hospital for relatively long periods of time in the course of 1.5 yr. The diagnosis was made on the basis of the high triglyceride content and the characteristic changes in the chief lip fractions of the plasma. Blood was obtained in the morning after a 16-hr. fast, heparinized an centrifuged at 4°C. Lipids were extracted from the plasma and fractionated. Normal av. values established in the particular laboratory were: phospholipids, 211.7 mg%; total cholesterol, 221.7 mg%; triglycerides, 96.0 mg%; free fatty acids, 617.7 µEq/liter. Five of these 36 patients had attacks of pancreatitis, 4 during hospital observation; 2 patients had 1 attack each and 2 had recurrent attacks. During these attacks the triglycerides were in high variable conc., 18, 12, 20, 8, 11, 7 times the normal values. The phospholipid content of the plasma and also the total cholesterol were also elevated to between 2 and 3 times normal. Afte the attack the triglycerides of the plasma fell to almost normal values or only 2-3 times norma but in a few wk. the plasma triglycerides again rose to high levels. Carbohydrate metabolism was obviously disordered in at least 1 instance with very high blood sugar values and urinary excretion of sugar. This diabetic state might have been a separate and distinct condition. Some hyperlipemic patients with pancreatitis also showed high blood and urinary diastase conc. The mechanism of this pancreatitis is unknown. Cholecystitis or cholelithiasis could be ruled out as a cause in all cases. Transien hyperlipemia secondary to pancreatitis was not observed in the clinic. Pancreatitis secondary to hyperlipemia is a recognizable entity.

9415 ANIMAL EXPERIMENTS ON THE PATHENOGENES OF PANCREATITIS. (Ger.) Schmidt, H. (U. Gottingen, Germany) and W. Creutzfeldt. Verh. Deutsch. Ges. Inn. Med. 72:719-725, 1967.

Incubation of rat pancreas homogenates at pH 5.2 causes activation of proteases even in the presence of trypsin inhibitors; these proteases may be identical with those demonstrable in the pancreas of animals with pancreatitis. To prov this the pancreatic tract was inj. with an activated pancreatic homogenate. Within the first 6 hr. after inj. an interstitial edema and a WBC infiltration occurred. Necrosis appeared very seldom and then in single cells only. After 24 hr. and morphological changes had returned to normal. No increase in serum enzyme activity was seen. By contrast, the spontaneous proteolytic activity of the pancreatic homogenate was still high; this activit was much higher than that found in the pancreas of animals after an inj. of taurocholate which has caused the development of the severest type of necrosis. A parallel between the conc. of active proteases and the degree of pancreatitis does not exist. The active proteases may play a role in the lysis of necrotic pancreatic tissue. The pancreatic tract of rats was next inj. with an active preparation of trypsin; thi was not followed by an activation of proteolyti enzymes in the tissues. Within 5 min. after th inj. of the trypsin, only 2% of its activity

ned due to the influx of serum trypsin
itors strong enough to cause edema; the
action of the trypsin was upon the secre-
ducts and not upon the gland cells. The
tion of toxic substances in the pancreatic
chyma may be the cause of necrosis; an
mal compound, a hemin pigment made by
ating a mixture of trypsin and blood for
., inj. into the pancreatic tract of dogs
s the severest, fatal, hemorrhagic type of
eatitis; inj. of a fresh mixture of trypsin
lood causes a milder degree of pancreatitis.
ame results occurred when these trypsin-
experiments were repeated in the rat.
substances, such as the split products of
hospholipids, can evoke strong cytotoxic
ions.

EXPERIMENTAL TRYPTIC PANCREATITIS WITH
INDIRECT AND DIRECT COOLING OF THE
. (Ger.) Nagel, M. (Johannes Gutenberg
ainz, Germany), F. K. Kössling and W.
rsieck. Med. Welt 18(12):698-703, 1967.

reatitis was produced in 42 dogs by the
llation of 20, 10, or 2 ml of a bile-
ated trypsin soln. (0.01 g trypsin in 10 ml
l saline) incubated with bile for 24 hr. at
. Indirect cooling was done (a) by freezing
tomach (refrigerant temperature in the
on -15°C for 40 min., and (b) cooling the
ch for 4-5 hr. with the coolant at 5-10°C.
irect cooling of the pancreas the refri-
ting balloon was laid upon the gland for an
val of 50 min.; the circulating medium had
mperature of -20°C. Adjacent organs were
ected by cloths. During and after the
ation a larger or smaller vol. of brownish-
le-colored edematous fluid appeared in the
reas. Serum amylase conc. increased un-
ted to the group: (1) inj. only with
erent vol. and pressures; (2) inj. with freez-
of the stomach; (3) inj. with cooling of the
ach, (4) inj. with direct cooling of the
reas. Similar changes occurred with serum
saminases and alkaline phosphatase. The
als in Group (1) showed a massive tryptic
reatitis, with a glassy or brownish edema,
rrhage, and necrosis of regional fatty
ue; circulatory disturbances were evident
ologically as were serous cell exudation,
ortion of the lobular parenchyma, and large
small areas of necrosis. In the ducts signs
ecretory stasis, inflammatory changes, and
al tearing of tissues were apparent. Dogs
he second group showed somewhat less edema;
proliferation of cells in necrotic areas,
reorganization of tissues. The third and
th groups showed no particular differences,
er macro- or microscopic, in response to the
ct or indirect cooling of the pancreas; in
ral Groups 3 and 4 resembled Group 1. The
inj. only seemed to survive indirectly with
vol., and pressure of the instillation;
e inj. with 20 ml at 50 cm H_2O pressure died
in 6 hr., whereas those receiving 2 ml at
30 cm H_2O pressure died after 3 wk. Freezing or cooling of the stomach, or direct cooling of the pancreas did not increase the duration of survival; if anything the duration was decreased by the hypothermic technics.

9417 ROLE OF THE CANALICULI IN THE GENESIS OF ACUTE PANCREATITIS. (EXPERIMENTAL STUDY ON RATS). (It.) Falcidieno, P. (U. Genoa, Italy), E. Nicora and A. L. Bertieri. Pathologica 58(863-864):225-242, 1966.

Among rats in which the common bile duct was ligated at the level of the hepatic hilus, 2 of 20 died of surgical complications. When the 18 survivors were sacrificed on day 12, dilatation of the common bile duct above the ligature was found with no evidence of pancreatic damage. However, when the common bile duct was ligated at the point of its debouchement into the duodenum, 16 of 20 died within 4 days, and when the remaining 4 of 20 were sacrificed on day 12, their pancreas showed the same characteristics: severe vasodilatation; generalized edema, which included interlobular spaces and extended to the omentum and mesentery; generalized hemorrhagic infiltration with areas of frank necrosis. Among rats in which the common bile duct was ligated at the level of the hepatic hilus and also below the 2 points at which the pancreatic ducts empty into it, 3 of 20 died within 4 days, with necropsy findings similar to those of the second group, just cited. When 17 of 20 were sacrificed on day 12, the pancreas were significantly diminished in vol. and increased in consistency; the ducts draining into the isolated area of the common bile duct were enormously dilated and filled with clear liquid; extreme interstitial edema and proliferation of perilobular and perivascular connective tissue was accompanied by marked dilatation of both canaliculi and acini. It is concluded that intracanalicular hypertension, accompanied by hypertensive biliary reflux and structural damage to the canaliculi and acini, may play a determining role in the pathogenesis and progress of acute pancreatitis, especially when rupture of the ducts initiates a process of pancreatic autodigestion, as it must do.

9418 NEW EXPERIMENTAL MODEL OF ACUTE AND CHRONIC RELAPSING PANCREATITIS. (Rus.) Toskin, K. D. Eksp. Khir. Anest. 11(6):12-13, 1966.

After a pararectal incision of the abdominal cavity in dogs, the duodenum was resected (beneath the pylorus), and the stump was sutured and peritonealized; this was followed by formation of an anastomosis between the stomach and the first loop of jejunum. A second incision, parallel to the first, was made, and a rectangular abdominal-muscular flap was removed from the lateral abdominal wall. A hiatus was made in the duodenal mesentery, with preservation of the vascular arcade; the rectangular flap was drawn through the hiatus and sutured in place. An intestinal loop was drawn through openings formed at the ends of the shortened flap, to which it was sutured. Finally, the duodenal loop was enclosed into a cutaneous tubule by a form of Filatov's graft. The graft was pinched, and one hr. later vomiting and discomfort were noted; 3-4 hr. later there was an increase of serum amylase and lipase which reached very high levels at 15-16 hr.; excitability decreased after 8-15 hr., and the animals expired between 18-36 hr. If pinching of the graft was discontinued within 12 hr., the dogs usually survived. Pathological changes were directly dependent upon the length of time that the graft was pinched. Acute edema of the pancreas, with gradually increasing cellular infiltration of the stroma, occurred after 3-6 hr. After 15-18 hr., there was parenchymatous necrosis of variable degree. Repeated pinching of the graft led to exacerbation of pancreatitis, leading in turn to chronic inflammation and, subsequently, pronounced fibrosis of the pancreas.

STUDIES WITH RADIOACTIVE COPPER (^{64}Cu
AND ^{67}Cu) IN RELATION TO THE NATURAL
RY OF WILSON'S DISEASE. (E.) Osborn, S. B.
s Coll. Hosp. Med. Sch., London) and J. M.
e. Lancet 1(7486):346-350, 1967.

take of radioactive Cu (^{64}Cu, ^{67}Cu) was
d in 24 patients with Wilson's disease:
in the asymptomatic stage of the disease,
signs and symptoms of hepatic disease, 9
urological symptoms but had received little
treatment, and 8, originally presenting
eurological disease, who had been receiv-
nicillamine for periods varying from 18 mo.-
Three of the latter were included in a
of 9 studied before the start of treatment.
l studies were made on 11 persons heterozy-
or the gene of Wilson's disease and on 17,
gous normal. The percentage of inj. radio-
Cu in the liver at 2 hr. was greatest in
ls, av. 59% (range 34-87%); the mean figure
terozygotes was 55% (range 25-65%). In
omatic Wilson's disease, the mean was 50%
42-61%); in hepatic Wilson's disease it
llen to 40% (range 28-52%), but in patients
isturbance of the CNS it was very low at
ange 14-27%). Patients who had received
ent had a higher av. uptake of 33% (range
) than those with untreated neurological
e. At 24 hr. the pattern of liver uptake
anged, the highest figures for liver Cu
found in patients with asymptomatic Wilson's
e, with a mean of 72% (range 48-96%);
were followed closely by heterozygotes,
n av. of 70% (range 49-83%), whereas in
ls the mean figure of 65% (range 35-85%)
little increase over the 2-hr. figure.
ts with the hepatic stage of Wilson's
e approached the normal value with a figure
(range 43-66%), whereas untreated neurolog-
atients again had a very low uptake, mean
ange 17-55%), and after treatment this
ed to a relatively high figure of 59%
36-92%). Determinations of the liver/thigh
at 15 min. showed a pattern of results
r to liver uptake at 2 hr., the highest
being found in controls and heterozygotes,
e lowest in untreated neurological patients
ome degree of improvement after treatment.
for plasma radioactivity at 2 hr.
sed as % of inj. Cu/liter showed very
r values for all groups in which liver Cu
was more than 40% at 2 hr., i.e., all
ts except those with untreated neurological
's disease. In controls, heterozygotes
tients with asymptomatic or hepatic Wilson's
e, mean plasma radioactivity at 2 hr. varied
n 1.2% and 1.8%, whereas in untreated neuro-
l patients the mean was 3.7%/liter; the dif-
e between the latter and other groups was
ighly significant. These findings suggest
he uptake of Cu by the liver is high in the
ptomatic stage of the disease; as the illness
sses through the hepatic to the neurological
there is a progressive fall-off in this
on by the liver, presumably reflecting saturation of the available binding sites for the metal. As the liver becomes saturated with Cu the plasma is cleared more slowly, and Cu can be detected more readily in other tissues. The capacity of the liver to conc. Cu can be restored, at least in some patients, by adequate long-term treatment with penicillamine.

9432 HEPATIC LESIONS IN PRECLINICAL WILSON'S DISEASE. IMPORTANCE OF DETECTION.

(Fr.) Bocquet, L. (Hosp. Sick Child., Paris), H. Jérome and R. Turpin. Sem. Hop. Paris 43(21): 1369-1374, 1967.

The determination of plasma ceruloplasmin levels and hepatic Cu conc. in specimens obtained by Menghini puncture-biopsy revealed the existence of preclinical Wilson's disease in 4 subjects (1 male and 3 female; age 3.5, 2.5, 10, and 10 yr., resp.) belonging to 3 groups of siblings (6, 2, and 4 subjects, resp.; total examined, 12 subjects). The 4 patients were asymptomatic but presented plasma ceruloplasmin levels (mg/100 ml of plasma) of 1, 1, 7, and 2, resp., and hepatic Cu levels (μg/g dry wt.) of 1571, 1322, 1389, and 764, resp. In addition, these patients presented important alterations of the cytoplasm and nucleus. The cytoplasm was granular and contained irregularly-arranged steatotic vesicles (minute in 2 patients and large in 2). Granular, yellowish, pigment deposits were observed in 1 patient. Small, intranuclear vacuoles were observed in all patients. Hepatocyte alterations included cell lysis in 2 patients and double nucleus in all. Fibrosis was present in 3 patients, while monocytic infiltration of portal spaces was slight in 2 and moderate in 2. Histochemical studies showed no Cu in Kupffer cells and epithelial cells of the bile ducts. Acid phosphatase determination of pigment granules revealed them to be lysosomes. The importance of early treatment with D-penicillamine is stressed. Fever and erythematous skin rash were observed in 3 of the 4 patients during treatment. The importance of early detection and continuous treatment is emphasized.

9433 STUDIES ON LEVELS OF PENICILLAMINE-INDUCED CUPRIURESIS IN HETEROZYGOTES OF WILSON'S DISEASE.

(E.) Tu, J.-B. (US Naval Med. Res. Unit No. 2, Taipei, Taiwan) and R. Q. Blackwell. Metabolism 16(6):507-513, 1967.

When the urinary Cu excretion and plasma Cu levels of 10 patients with Wilson's disease (homozygous group) were compared with that of 5 sets of parents of patients with Wilson's disease (heterozygote group) and 26 normal controls before and after 1 g oral doses of DL-penicillamine after the morning meal a diagnostic distinction was seen which would separate the heterozygote group from that of the homozygous one. The mean values for the urinary Cu excretions of the 3 groups before penicillamine differed significantly from each other: the controls ranged from 6-57 µg/24 hr., the heterozygote group, 19-120 µg/24 hr. and the homozygote group 120-560 µg/24 hr. All subjects in the 3 groups showed distinct increases in their urinary Cu excretions after ingestion of 1 g of penicillamine and here the ranges of the homozygotes and heterozygotes were completely separated; the mean for the 2 groups was 2330 µg/hr. and 1000 µg/hr, resp. This suggests a slight tendency for tissue Cu accumulation in the heterozygote group. When these values are plotted with total plasma levels the 2 groups were even more clearly separated. In both groups the urinary Cu excretion before or after the drug appeared to be independent of the individual's plasma Cu level. The range of the normal homozygote controls still overlapped with that of the heterozygote group, but the mean was significantly lower.

9434 DEMYELINATING PERIPHERAL NEUROPATHY AND LIVER DISEASE. (E.) Dayan, A. D. (Gen. Hosp., Southampton, England) and R. Williams. Lancet 2(7507):133-134, 1967.

Of 10 patients (8 men, 2 women; 38-64 yr. old) studied by nerve biopsy or at autopsy, 4 had alcoholic cirrhosis, 2 had cryptogenic cirrhosis, and 1 each had partial nodular transformation of the liver, active chronic hepatitis, hemochromatosis and acute hepatic necrosis. Neuropathy was mild and apparent only in the lower extremities; signs were restricted to absent knee or ankle jerks with or without sensory loss. A sural-nerve specimen was obtained at biopsy in patients with a clinically apparent neuropathy or at necropsy. Evidence of collateral circulation was found in 4 patients, 1 of whom had a lienorenal shunt for 15 yr. By examination of isolated teased nerve-fibers, evidence of segmental demyelination was found in all nerves examined from each of the 10 patients. It is suggested that the nerve damage might have been due to unidentified toxic metabolites or to disordered insulin metabolism caused by the liver damage.

9435 INFLUENCE OF PARTIAL HEPACTECTOMY ON METASTASES OF WALKER-256 CARCINOMA IN PARABIONT RATS. (Rus.) Khundanov, L. L. (Inst. Exp. Biol., Acad. Med. Sci., Moscow) and I. N. Maiskii. Biull. Eksp. Biol. Med. 63(3):104-106, 1967.

Under conditions of parabiosis (performed by peritoneal anastomosis) in male, August-strain rats (60), hepatectomy stimulated the metastatic process of ascitic carcinoma Walker-256; in addition, formation of metastases was more intensive with a larger inoculum of tumor cells, and the time of traumatization had a significant effect on the metastasizing process but the
length of parabiosis had no effect on it. In
Group 1 (270 days of parabiosis), with hepate
tomy in partner B performed simultaneously wi
the inoculation of 150,000 or 250,000 tumor
cells to partner A, the av. number of metasta
in the liver of partners A and B was 33.0 and
1.7, or 56.3 and 3.7, resp. In Group 2 (14 d
of parabiosis), with hepatectomy in partner B
performed 1 mo. before inoculation of tumor
cells (the same quantity) to partner A, the a
number of metastases was 38.6 and 0, or 57.8
0, resp.; in Group 3 (14 days of parabiosis),
hepatectomy in partner B performed simultaneo
with the inoculation of tumor cells to partne
the av. number of metastases was 38.0 and 2.0
54.3 and 4.6, resp. The av. number of liver
metastases in controls (who were not hepatect
mized) of Group 1, in partners A and B, resp.
was 36.0 and 0 for the smaller inoculum and
46.0 and 0, resp., for the larger inoculum.
Group 3, resp. values were 40.5 and 0 for the
smaller inoculum and 49.5 and 0 for the large
inoculum. In Groups 1 and 3, the metastatic
nodes were larger in partner B.

9436 CHEMOTHERAPY FOR MALIGNANCY OF THE
LIVER BY SHORT-TERM DIRECT INFUSION
THE HEPATIC ARTERY. (E.) Farmer, R. G.
(Cleveland Clin., Ohio), E. J. Filson and E.
Buonocore. Cleveland Clin. Quart. 34(2):
89-95, 1967.

A satisfactory technic is described for intra
hepatic arterial cancer chemotherapy, but the
results obtained on 16 patients with malignan
neoplasms, either primary or metastatic,
indicated that the treatment was unsatisfacto
Of the 16 patients, none achieved a true
objective remission from the disease and only
had a subjective response with relief of pain
and improvement in performance status when
evaluated 6 wk. after infusion. These 8 also
survived longer than 6 mo. but it is question
if this was due to the infusion, as they
received maintenance chemotherapy during this
time. For the infusion, 5-fluorouracil (15 m
body wt. was admin. daily over a 12-hr.-perio
7-11 days in 14 cases (wherein the most commo
lesion was carcinoma of the colon) while 2
others (1 with malignant melanoma and 1 with
myosarcoma of the stomach) received a daily
combination of 5 mg of 4-amino-N-10-methyl
pteroylglutamic acid and 1.5 mg/kg of body wt
of cyclophosphamide. The interval between
diagnosis and infusion ranged from just short
afterward to as long as 7 yr. later. The
series comprised 11 men and 5 women, whose ag
ranged from 32-73 yr., who previously had not
received treatment with the exception of 1 ca
of roentgentherapy of several mo. duration an
1 case of systemic admin. of chemotherapy.
general, the infusion was well tolerated.

9437 HEPATOMAS OF THE MOUSE. 1. HEPATOM
IN ONE LINE OF ALBINO MICE. (Fr.)

illon, J. C. (Pasteur Inst., Paris), I. ouroulinkov and M. Guérin. Path. Biol. (Paris) (5-6):241-249, 1967.

ring observations on cutaneous cancer in mice, ecords were kept on hepatic tumors also occur-ng; 726 males and 715 females were autopsied d liver tumors were found in 106 males (14.6%) d 17 females (2.4%). The first tumors occurred males aged 12-13 mo.; these first such owths did not appear in the females until -21 mo.; the greatest incidence for both sexes s during mo. 22 and 23. These spontaneous mors showed no preferential localization; in instances the tumors were multiple and varied om 1-30 mm in diameter, mostly spherical, and ll delineated. They had a pulpy homogenous nsistency, differentiated from the normal renchyma by their clearer color and richer rface vascularization; the larger ones were rked by creases and hemorrhagic cavities or d zones of necrosis. Only 7 possible metastases re observed in 6 males and 1 female; small dules on the lung and in 1 case metastases in e perirenal adipose tissue. Of the total 123 mors, 104 were examined histologically. The mors were encapsulated with connective tissue; e tumor tissue itself consisted of slightly attened hepatocytes; in some instances it was ssible to distinguish peripheral and central nes. The cells of the tumor contained cyto-lasmic inclusions, spherical, hyaline, eosino-ilic, described as waxy bodies; these were ery numerous and some seemed to possess a entral kernel. The cells of the central zone f the tumors were without waxy bodies and eemed like normal hepatocytes; the mitotic igures favored the inclusion of these tumors in e adenomas. The older tumors showed large areas f necrosis, hemorrhage, fatty infiltration, and yeloid bodies; giant cells were sometimes noted. ssible etiologic factors are discussed. It is uggested that the mouse is an excellent subject r studies of factors associated with spontaneous umor development.

438 VARIOUS ASPECTS OF HEPATIC FUNCTION IN THE AGED SURGICAL PATIENT. (It.)
e Vincentiis, E. (U. Naples, Italy), B. Tardio nd B. Papa. G. Ital. Chir. 22(4):437-446, 966.

epatic function was studied in 150 surgical atients divided into 3 groups according to age: 0-44 yr. (Group 1); 45-64 yr. (Group 2); 65-80 r. (Group 3). Besides the Takata-Ara and underly-Wuhrmann tests of hepatic function, the rinary excretion of N_1-methylnicotinamide was etermined (modified Huff-Perlzweig fluorimetric ethod) basally and after oral loading with icotinamide alone (200 mg/day twice), then icotinamide (same dose) and methionine (2 g) or 2 days. Basal values of urinary excretion f N_1-methylnicotinamide of patients on normal ospital diet were practically the same in atients of Groups 1 and 2, but were perceptibly lower in patients of Group 3. Hepatic function tests were positive in 10% of patients of Group 1, in 32% of Group 2, and in 45% of Group 3. After loading with nicotinamide, urinary excretion of N_1-methylnicotinamide increased markedly in patients of Groups 1 and 2 without further increase after the addition of methionine. Patients of Group 3 had a very moderate increase in urinary excretion of N_1-methylnicotinamide after nicotinamide loading, but a very marked increase (similar to that seen in patients of the other 2 groups after nicotinamide) after the association nicotinamide-methionine. Results indicate normal methylating ability in patients between 20 and 64 yr. old, and loss of methylating ability in patients of Group 3. It is concluded that a more intense vitamin and liver protective therapy is needed in older surgery patients.

9439 EXPERIMENTAL STUDIES OF PROCEDURE IN ORTHOTOPIC HOMOLOGOUS TRANSPLANT OF THE LIVER IN DOGS. (It.) Abbate, M. (U. Naples, Italy), A. Infranzi, R. Nigro, C. Lombari, T. Masturzo, D. Mori and G. Masturzo. Gazz. Int. Med. Chir. 72(9):736-778, 1967.

Among 10 dogs subjected to conventional methods of orthotopic, homologous liver transplant, operative times ranged from 3.25-5 hr.; the period of total ischemia ranged from 45-60 min.; that of partial ischemia, for 60-110 min. One of the 10 died during surgery; 2, immediately after surgery; 3, within 4-12 hr.; 2, within 24 hr.; 2, on the third and fourth day, resp. Among 10 other animals subjected to the same operation, but with revascularization of the transplanted organ before anastomosis was completed, achieved by joining the hepatic arteries of the donor and recipient, operative times ranged from 3-4.5 hr.; total ischemia lasted for 40-60 min.; partial ischemia, for 60-100 min. Two of 10 died during surgery; 3, within 3-12 hr.; 2 within 24 hr.; 2, on the third and fourth days, resp.; 1 on the fifth.

9440 EXPERIMENTAL HOMOTRANSPLANTATION OF THE LIVER. (Rus.) Lopukhin, I. M. (2nd Moscow Med. Inst.), I. E. Berezov, I. V. Egorov, A. S. Ermolov, E. M. Kogan, S. M. Kremli, K. M. Lakin, M. D. Lapin, I. M. Sapelkina, N. M. Khait, E. M. Iukhtina and E. E. Udovskii. Eksp. Khir. Anest. 11(6):3-11, 1966.

A right-sided flap thoraco-abdominal approach with resection of the arcus costarum and ribs 8-11 at the scapular line permitted a better approach to the liver and its vasculature in 51 mongrel dogs; in these animals, the vena cava was resected and sutured into the lower end of the liver, while its upper segment was fixed with clamps. Hypothermia, or perfusion of the isolated liver with a cooled fluid through the portal vein and hepatic artery, preserved the viability of the graft; in this manner, a uniform cooling of up to 7.5-10° during a period of 15-20 min. was obtained. Transplantation of the donor's liver to the recipient without removal of its own liver was attempted in 22 dogs. In 16, the liver was grafted into the left half of the abdominal cavity with or without removal of the spleen; 4 died during surgery and 12 died 4-52 hr. after surgery, of which 8 were due to hemorrhage developed from the overfilling of the donor's liver with blood. In 6 dogs, the liver was grafted into the right iliac region and 2 of these died in the first day of the experiment from blood outflow block and hepatic bleeding, while 4 survived from 2-8 days, showing a preserved function of the liver. Removal of the liver was accompanied by an increased fibrinolytic activity of the blood, as revealed in 26 dog-donors; with high fibrinolysis there was no clotting. In most dogs after implantation of the second liver, blood coagulation approached initial values or was increased; the latter occurrence predisposed to thrombus formation, which could be reduced by anticoagulants. Within 2 days after surgery the implanted liver increased in size and was dense and plethoric; toward 4-7 days, its size decreased, and remained dense showing some small hemorrhagic foci. Histologic study revealed the following changes in the donor's liver: destruction of the parenchyma, nuclear pyknosis, cellular vacuolization, vascular infiltration and mononuclear infiltration of the vessels. In the recipients' liver, only slight structural changes were seen; edematous parenchyma, vacuolization and destructive processes in the cells of the organ were slight.

9441 HETEROTOPIC LIVER TRANSPLANTATION AFTER BILIARY OBSTRUCTION. (E.) Gliedman, M. L. (U. New York, Downstate Med. Ctr., Brooklyn), L. Popowitz, J. Pangan, P. K. Kottmeier, K. E. Karlson, A. S. Josephson and S. Minkowitz. J. Pediat. Surg. 2(2):144-154, 1967.

Following cholecystostomy and construction of an external biliary fistula, auxiliary livers derived from puppies were grafted into adult dogs, with and without concomitant immunosuppressive therapy with azothioprine, methotrexate, actinomycin-C, prednisone or radiotherapy, alone or in various combinations, or concomitant treatment with ^{35}S-methionine, epsilon-aminocaproic acid or antilymphocyte serum. The most effective immunosuppression was obtained by pretreatment with azothioprine and prednisone (each at 100 mg/day four times), followed by transplant and then by azothioprine (6 mg/kg/day), prednisone (100 mg/day), methotrexate (0.1 mg/kg every other day) and actinomycin-C (7-10 μg/twice wk.). The longest graft survival was 1 mo., with complete absorption of the rejected graft by surviving animals within 6 wk. after cessation of function. Some animals under immunosuppression survived graft rejection and absorption, although these were uniformly fatal in untreated animals. All immunosuppressed animals showed a gradual loss of hepatic tissue and vol. in the transplanted liver, accompanied by fibrinoid degeneration in the arterial wall. In a correlative study, karyotypes of peripheral blood leukocytes of the dog, dingo and coyote were indistinguishable (78 XX,XY); the karyotype of the fox was 38 XS, XY; that of the pig was 38 XX, XY. Immunoelectrophoretic studies also confirmed complete serologic cross-reactivity between the dog and fox. When 7 coyote and 5 dingo liver transplants were made into dogs, the longest survival was 12 days. When 14 successful fox-to-dog transplants were made, the longes period of graft function under intensive immunosuppression was 22 days, with survival of 5 of 14 animals. Swine-to-dog transplants were uniformly and rapidly fatal. Note is made that the functioning of the auxiliary, transplanted liver could not be assayed satisfactorily by liver function tests of the host, because the host's liver masked graft dysfunction and the immunosuppressive agents employed were hepatotoxic in their own right.

9442 HETEROTOPIC AUXILIARY LIVER TRANSPLANTATION. PART II. A TECHNIQUE FOR HETEROTOPIC PARTIAL LIVER HOMOTRANSPLANTATION IN DOGS. (E.) Van Der Heyde, M. N. (Univ. Hosp., Leiden, Netherlands). Arch. Chir. Neerl. 18(4):285-291, 1966.

Dogs received 1,000,000 U penicillin and 125 mg tetracycline daily for 5 days before operation. Neither donor nor host received any other drugs, especially immunosuppressive agents. A midline incision was made under anesthesia. Splenectomy was performed; the distal portion of the inferior vena cava dissected without ligating lumbar veins; the right iliac artery was dissected and freed. The left carotid artery of the anesthetized donor was cannulated for rapid exsanguination. After midline laparotomy, the spleen and stomach were displaced upwards and to the right, and the celiac, splenic and left gastric arteries were exposed on the left. The latter 2 were ligated and cut; the celiac dissected free; the first 3-4 cm of the hepatic artery dissected free without removal of surrounding lymph vessels and nerve fibers. Division of the hepatoduodenal ligament was followed by ligation and division of the right hepatic duct, common bile duct, pancreaticoduodenal artery and pancreaticoduodenal vein. The hepatic artery and portal vein were dissected free. The right liver lobes were displaced, the inferior vena cava exposed. A polyethylene catheter (diameter 2 mm) was connected to physiological saline (15°C with 1 g/500 ml procaine). The superior mesenteric artery and portal vein were ligated; the catheter quickly inserted in the latter in the direction of the liver hilus; the portal vein divided; the donor exsanguinated after perfusion began. The celiac artery was clamped at its aortic origin and divided obliquely; a thoracic midline incision was made; the diaphragm

:tioned just in front of and around the vena va, which was clamped proximally and distally the liver. The liver was then removed entirely th the retrohepatic vena cava. The gallbladder s incised to prevent bile stasis. The smaller ft hepatic vein of the transplant was ligated; e larger one divided on the liver surface; the ver rotated to expose the hilus; the right anch of the portal vein ligated and cut. The ssue bridge between the right and left lobes s cut, the vena cava and right lobes separated from the transplant; the donor's hepatic in anastomosed to the host vena cava; the ght iliac artery anastomosed end-to-end to the ansplant celiac artery. Careful hemostasis llowed. The operation is interrupted to enable st to recover from vascular increase; 300-500 donor blood is given. The operation is completed with cholecystojejunostomy. The simplic- / and size advantages of this technic are ressed.

43 HETEROTOPIC AUXILIARY LIVER TRANSPLANTATION. PART III. FUNCTIONAL COMPETITION JSE OF ATROPHY OF THE AUXILIARY LIVER TRANS- ANT. (E.) Van Der Heyde, M. N. (Univ. Hosp., iden, Netherlands), M. Vink, H. Stol, H. W. :ke and S. W. Schalm. Arch. Chir. Neerl. (4):293-298, 1966.

terotopic liver transplantation was performed Group 1 (10 dogs). Cholecystojejunostomy was t performed but bile drainage was accomplished cannulation of the cystic duct. In Group 2 (20) terotopic transplantation was accomplished with olecystojejunostomy, and the host liver was ovided with an end-to-side portacaval shunt. attempt was made to achieve rapid complete struction to drainage of bile from host liver cholecystectomy and ligation and division of trahepatic bile ducts, separately, close to e liver hilus. Immunosuppression was by admin. azathioprine, 6-8 mg/kg from day of operation rough the fourth postoperative day, 3-5 mg/kg days 5-20, 2-3 mg/kg subsequently; Actinomycin, µg i.v. on day of operation and postoperatively days 5, 10, 15, 20, 25.; prednisone initially r a brief period where a rejection reaction s considered possible; splenectomy in all ses. Antibiotics used were: donor, 1,000,000 penicillin and 125 mg tetracycline daily for 5 ys immediately before operation; host, same se for 5 days postoperatively and 1 g neomycin o. during 3 preoperative days. Wt. loss companying immunosuppressive treatment was mbatted by a diet of 2500 calories daily 0-30 g protein). In Group 1, 1 survived only days, the rest for 15-35 days. Bile flow of 6 ml/hr. was relatively constant, diminished 5-7 days, and stopped after 11. There was no rrelation between bilirubin conc. and decrease bile production. After the end of bile oduction, liver punctures always showed normal croscopic structure without signs of rejection. Group 2 there were 6 early deaths from related causes, 2 rejections, 3 atrophies, and 9 retained wt. or hypertrophied. In both groups, conditions for transplantation were unfavorable because dogs had to overcome a period of hypothermia and ischemia, immunological aggression, and portal ischemia. Operation on host liver made transplant more favorable physiologically than host liver. Results showed that liver transplants can continue to function without perfusion with portal blood.

9444 PATHOLOGICAL, ANATOMICAL, HISTOLOGIC, AND HISTOCHEMICAL CHANGES IN LIVERS PERFUSED WITH HETEROLOGOUS BLOOD. (It.) Ferraris, R. (U. Ferrara, Italy), G. Motta, P. Georgacopulo and S. Guerrieri. Minerva Chir. 22(5):238-243, 1967.

Isolated fragments of swine liver, derived *in vivo*, were washed preventively with heterologous blood throughout the entire isolation procedure, then perfused directly with cooled, oxygenated, heterologous blood for varying periods of time prior to pathologic, histologic and histochemical analysis. It was found that such fragments could be kept alive for presumably indefinite periods of time, with normal metabolic function and with no evidence of tissue damage, provided an adequate O_2 supply was available from the beginning and maintained without interruption. It was also found essential to maintain the pH of the heterologous blood supply, which tended to drop spontaneously during the course of perfusion, within a range of 7.2-7.4. Any drop below 7.2, the minimal level compatible with normal O_2 transport, led very quickly to irreversible cell damage. (See also: 9445 and 9446.

9445 IMMUNOLOGIC CONSIDERATIONS IN PERFUSION OF THE ISOLATED LIVER WITH HETEROLOGOUS BLOOD. (It.) Azzena, G. F. (U. Ferrara, Italy), R. Ferraris and E. Tabone. Minerva Chir. 22(5): 244-246, 1967.

In host dogs whose blood supplies were used for 150-min. isolated perfusions of swine livers, no antiliver antibodies could be demonstrated, even after the experiment had been repeated twice, at intervals of 25 days. However, the host developed antiserum antibodies against serum elements remaining in the vascular system of the perfused organ, despite prior washings with saline. These were demonstrable after a single perfusion, increased progressively following a second and a third. There was no evidence of immune response to tissue elements of the perfused organ. (See also: 9444 and 9446.

9446 ELECTRON MICROSCOPIC STUDIES OF SWINE LIVER PERFUSED WITH HETEROLOGOUS BLOOD. (It.) Martines, G. (U. Ferrara, Italy), G. F. Musacci, G. Motta, R. Ferraris and P. Georgacopulo. Minerva Chir. 22(4):153-156, 1967.

Electron microscopic studies were made of isolated swine liver perfused for 15 and 150 min. with dog blood. (See also: 9444 and 9445). No significant changes were evidenced after 15-min. perfusion. After 150 min., hypertrophy and swelling of the mitochondria appeared to confirm a blockage of oxidative phosphorylation. The vol of the nucleus was decreased in relation to the cytoplasm, with conc. of chromatin along the edges of the nuclear membrane. The cytoplasm contained autophagocytic vacuoli. There were clumpings of ergastoplasmic membrane in the cytoplasm and the canaliculi were extremely short and abnormally distributed. A virtually complete depletion of cellular glycogen was also in evidence. Note is made that none of the changes reported appeared to be sufficiently advanced to jeopardize survival of the isolated organ.

9447 SPLANCHNIC HEMODYNAMICS AND THE VARIOUS DEVELOPMENTAL PHASES OF FATTY DEGENERATION OF THE LIVER. (It.) Bevilacqua, G. (U. Milan, Italy), G. Gallioli and A. Lotto. Minerva Chir. 22(6):322-334, 1967.

In an effort to clarify the hemodynamic changes which usually accompany fatty liver, histological, histochemical and ultramicroscopic studies were performed in 25 patients with fatty liver (11 with chronic steatotic hepatitis, 8 with cirrhosis due to steatosis, 4 with pure steatosis, and 2 with microcicatricial fatty liver. Differing liver morphology was found in these cases: massive reticuloendothelial infiltration, lipid infiltration of hepatocytes, increased density and rigidity of connective tissue, and differing appearance of hepatic sinusoids. In some cases, irregular, large, areas of sinusoidal dilatation and congestion were frequent; in others, the vascular areas of the lobe were collapsed. This variability of sinusoidal resistance leads to sporacic changes in portal pressure. In the author's series, the usual effect of steatosis on the vascular network was represented by portal hypertension with increased suprahepatic occlusion pressure. In only 1 case was the increase very slight, probably because of a prevalent presinusoidal localization of the circulatory block. In 1 patient, a long period of treatment with hepatoprotective agents and abstention from alcohol was followed by a decrease in portal hypertension and return to normal of suprahepatic occlusion pressure values; subsequent ingestion of large quantities of alcohol caused a flare-up of the degenerative disease with recurrence of portal hypertension, increased suprahepatic occlusion pressure, and massive hemorrhage. It is concluded that the lobular changes induced by fatty degeneration are reflected hemodynamically by a block of portal flow at various levels and consequent increased portal hypertension. In initial stages, portal pressure values may change depending on the course of the degenerative disease. However, these variations become less frequent due to the prevalence of sclerotic changes and lobular regeneration, until a definite, irreversible hypertensive state is reached. Three illustrative case reports are included.

9448 THE EFFECT OF CAFFEINE ON FAT METABOLIS IN LIVER DISEASE. (Ger.) Zeller, W. (U. Erlangen-Nuremberg, Germany) and H. P. T. Ammon. Z. Gastroent. 5(2):84-89, 1967.

The blood levels of free fatty acids in response to caffeine were studied in 20 patients with different disorders of the liver, all with more or less depressed hepatic function. Caffeine (250 mg) was admin. by inj. and p.o. in fasting individuals; blood samples were taken at 0.5 hr intervals for 3 hr. and 3 lipid fractions determined: (1) free fatty acids, (2) esterified fatty acids and (3) total cholesterol. Blood samples were also taken from the hepatic patients at 4, 6, 8, and 10 hr. after admin. of caffeine. Ten normal subjects were treated in exactly the same manner; blood samples were collected for 3 hr. only. The same procedure was followed in 5 control persons who received caffeine-free preparations. All requirements of a double blind test were fulfilled. After i.v. inj. of caffeine into healthy subjects, the av. free fatty acid conc. rose from 0.48 to 0.83 μEq/ml in 2 hr., falling to 0.63 μEq/ml at 3 hr. still significantly increased. Inj. of caffeine free physiological saline caused no change beyond the limits of experimental error. The inj. of caffeine into the liver patients caused a rise of free fatty acids from the av. 0.92 μEq/ml (a high value) to 1.94 μEq/ml; 10 hr. after inj. the serum level of free fatty acids was still higher than before the test. Oral admin. of caffeine in the controls caused an av. rise from 0.44 to 1.03 μEq of free fatty acids in 3 hr.; the comparable figures for the liver disease patients were a rise from 1.14 to 1.69 μEq/ml of free fatty acids in 3 hr. The conc. of esterified fatty acids and total cholesterol in the serum of the liver patients were greater than normal but were not influenced by caffeine, at least in a dose of 250 mg. These tests were repeated on 2 other groups of 32 liver patients and 31 healthy persons with the same results.

9449 AN ENCEPHALITIC SYNDROME ACCOMPANYING FATTY DEPOSITION IN THE LIVER. (Ger.) Čihula, J. (Fac. Med., Hradec Kralove, Czechoslo kia), I. Drašner, I. Dvořáčková, V. Vortel and V. Hroch. Z. Ges. Inn. Med. 22(1):14-21, 1967.

Eleven cases of a syndrome among infants and young infants are reported; the chief clinical symptoms have been (1) emesis, (2) mental confusion, (3) disturbances in breathing, (4) cramps, (5) changes in muscle tonus, (6) fever, (7) changes in visual reflexes, (8) changes in shape and reaction of pupils, (9) trismus, (10) circulatory disturbances, (11) swelling of the

er, (12) exanthema; (1-3) occurred in 11 sub-
ts, (4 and 5) in 10, (6-8) in 9, and (9) in
(10) in 5, (11) in 4, and (12) in 2 patients.
laboratory findings were diverse in many
pects; WBC were high in some cases, normal in
ers; in 1 case a blood glucose conc. of 19.6
was reported whereas another patient had
mg% and in a third blood sugar was reported
mg%. Similar variations occurred in other
ameters; in 2 cases the serum transaminases
e found to be high. The main pathological,
tologic and anatomic findings were fatty
iltration of the liver, cerebral edema, and
erplasia of the lymphatic system; the liver
wed round cell invasion. Macrophages were
sent in the alveoli, in the bronchi, the brain
in the sinuses of lymph nodes. In 1 case
e 3 adenovirus was isolated from 3 different
sues. It is suggested that a virus is the
se of this fatal syndrome. The clinical
gnosis was acute encephalitis; 8 had been
osed to hepatitis. The duration of the ill-
s was short, 3-10 days (av. 6 days); 6 patients
e male, 5 female; there was no special
sonal incidence in these cases.

0 DIAGNOSTIC SIGNIFICANCE OF THE EMBRYO-
SPECIFIC α-GLOBULIN DETERMINATION IN
BLOOD SERUM OF HEPATOMA PATIENTS. (Rus.)
arinov, Iu. S. (Astrakhan Med. Inst., USSR)
A. M. Nogaller. Vop. Onkol. 12(12):26-29,
6.

ults of clinical, immunochemical and patho-
tological analysis of 106 patients with
ious liver diseases (cancer, 17; viral
atitis, 24; chronic hepatitis, 18; cirrhosis,
acute and chronic cholecystitis, 6;
inococcus, 2; and abscess, 2) revealed that
embryospecific α-globulin is a valuable method
the intravital diagnosis of hepatoma. In 5
ients (42-59 yr. old) who expired 1 mo.-1.5
after the onset of clinical symptoms of
atoma (3 with cirrhosis, 2 without cirrhosis),
content of embryospecific α-globulin varied
ween 2.6-5.3%, as compared to 100% in the
wk.-old embryo. Apparently the embryo-
cific α-globulin also appeared in the serum
early stages of the hepatoma; this can be of
erest for the earlier diagnosis of hepatoma.
3 patients with cholangioma, the embryo-
cific α-globulin could not be detected in the
um. The embryospecific α-globulin test was
ative in 9 patients (37-53 yr. old) with
astatic cancer of the liver (metastases from
stomach in 3, from the intestine in 2, from
lungs in 2, and from the pancreas in 2) of
o.-2 yr. duration. More than 200 tests on
sera of healthy persons gave negative re-
ts for the embryospecific α-globulin test.

1 COMPLEMENT-FIXING LIVER ANTIBODIES. II.
OCCURRENCE IN A MATERIAL OF PATIENTS
H CHRONIC HEPATITIS. (E.) Norup, G. (State
um Inst., Copenhagen.). Acta Path. Microbiol.
nd. 69(3):404-416, 1967.

Complement-fixing antibodies were evident in the sera of 29.6% of 135 patients with hepatic cirrhosis in the presence of suspensions of normal human liver biopsies and/or normal liver from rhesus monkeys. Of those with positive results for these 2 liver antigens, 93% were from patients with chronic hepatitis of viral or unknown etiology. Of the remaining 3 positive sera, 2 were from patients with alcoholic cirrhosis and 1 from a patient with secondary biliary cirrhosis. The study included 48 patients with posthepatic cirrhosis, 50 with cryptogenic, 29 with alcoholic and 8 with biliary cirrhosis; 56% of the patients were over 60 yr. of age. Of 92 sera tested, (including the above-mentioned positive ones) 14 reacted positively to normal human liver necropsy inj. In addition, a positive complement fixation was also found in 18.8% and in 14.1% of the sera using normal kidney tissue and thyrotoxic thyroid glands, resp., as antigens. The complement-fixing liver antibodies were nonspecific and nonorgan specific. The pattern of organ reactivity was constant for a given patient, but varied arbitrarily from 1 patient to the other.

9452 ANTI-GAMMA-GLOBULIN FACTORS IN LIVER DISEASES. (Ger.) Meyer Zum Büschenfelde, K. H. (Johannes Gutenberg U., Mainz, Germany), U. Hopf and V. Bokisch. Verh. Deutsch. Ges. Inn. Med. 72:683-688, 1967.

A search for antibodies was carried out on the sera of 169 patients with defined liver diseases, acute hepatitis, chronic hepatitis, and liver cirrhosis. The following tests were applied to the serum of each patient: (1) Rheumafactor Latex test; (2) the Waaler-Rose test; (3) passive hemagglutination with tanned O-rh RBC which were loaded with Cohn's Fractions II, both species-specific and species-unspecific; (4) the inhibition test; (5) column chromatography on Sephadex G 200; the separated entities were tested for antibody and antigen reactions. Considering all the tests applied and the care exercised in back checking, the comparison of factors with factors previously known, and the use of immunologic cross reactions, the results were uneven and were summarized: (1) Rheuma factor-like entities with anti-γ-globulin properties arose irregularly in the course of the liver diseases studied. After inactivation of sera in the Latex test, they were no longer demonstrable. The Waaler-Rose test was generally negative. The factors reacted the strongest with aggregated human γ-globulin A heat-labile fraction was destroyed at 56°C. (2) Rheuma factor-like entities arising in the sera of patients with these liver diseases were not identical with other antibodies arising during liver disease. (3) The factors were not single entities and showed a different spectrum of immunologic cross-reactions with species nonspecific γ-globulins. A complete inhibition of the reaction with human γ-globulins did not occur under the varying conditions employed.

9453 LUPOID HEPATITIS: COMPUTER ANALYSIS DEFINING "HEPATITIS" AND "CIRRHOSIS" PHASES AND RELATIONSHIPS BETWEEN HEPATOCELLULAR DAMAGE AND IMMUNE REACTIONS IN THE LIVER. (E.) Goldstein, G. (Roy. Melbourne Hosp., Australia) and I. R. Mackay. Aust. Ann. Med. 16(1):62-69, 1967.

The interrelationships between histopathological, clinical, biochemical and serological indices in 30 patients with lupoid hepatitis were analyzed by a digital computer which was used to calculate 225 correlation coefficients. The study defined 2 groups of significantly interrelated histological indices corresponding to "hepatitis" and "cirrhosis" phases of the disease. The hepatitis phase comprised liver cell necrosis, plasma cell accumulation and Küpffer cell hyperplasia; the cirrhosis phase comprised loss of architecture, bile duct proliferation, fibrosis, and lymphocyte and plasma cell accumulation. The study also defined significant interrelationships in the hepatitis phase between hepatocellular damage and an immune reaction as shown by plasma cell accumulation in the liver, lupus erythematosus cell positivity and γ-globulin increase in serum. At least in part, the immune reaction is to antigens of damaged hepatic cells; it may be entirely a consequence of damage from a primary process, such as a virus infection, or it may be an autoimmune cause of continuing cell injury. The analysis did not discriminate between these 2 possibilities.

9454 HEPATIC PUNCTURE BIOPSY GUIDED BY SCINTISCANNING WITH COLLOIDAL ^{198}Au. (It.) Bazzanella, F. (U. Perugia, Italy), U. Senin and R. Palumbo. Settimana Med. 54(21):1155-1162, 1966.

Patients with suspected primary or metastatic liver malignancy (based on routine liver function tests and objective examination) were subjected to liver scintiscanning by i.v. inj. of 250 µc of colloidal ^{198}Au. In 10 patients, "cold" areas were delimited on the skin of the hepatic region by means of dermatographic pencil, guided directly by the scanning procedure. In the patients in whom no "cold" areas were evident, needle-puncture biopsy of the liver was performed at the level of the VIII-IX intercostal space according to Menghini's method. In the 10 patients who presented "cold" areas, needle-puncture biopsy was performed at the level of the areas delimited on the skin of the hepatic region. In all of these patients, biopsy revealed the presence of neoplastic tissue. Histologic examination confirmed the presence of carcinoma (4), metastatic carcinoma (4), metastatic sarcoma (1), and metastatic seminoma (1). Two patients are described in detail. The constant positivity of results obtained with this method, as well as the simplicity of the procedure, have prompted the authors to recommend its routine use in all clinical cases in which liver malignancy is suspected.

9455 LIVER SUBSTITUTION THROUGH HOMOLOGOUS AND HETEROLOGOUS EXTRACORPOREAL LIVER PERFUSION. (Ger.) Boeckl, O. (Regional Hosp., Salzburg, Austria), E. Hell and G. Zimmermann. Z. Ges. Exp. Med. 143(3-4):362-366, 1967.

The excised liver of hogs was placed in a perfusion apparatus with blood from another hog (homologous perfusion); the apparatus maintaine proper temperature, and oxygenated the blood; acidosis was corrected with 10% NaHCO$_3$ soln., and alkalosis with lysine soln. The afferent vessel was the portal vein and the efferent, th vena cava. The portal pressure was 22-65 mm Hg and the min. vol. 380-670 ml (0.5-0.8 ml/g/live min.). The perfusion lasted 3 hr. usually; some prolonged perfusions were done. Heterolog perfusion was carried out in exactly the same manner after the hog blood had been washed out from the liver by physiological saline cooled t 4°C. The perfusion apparatus was filled with human blood from the blood bank. The parameter tested for comparison between the homologous an heterologous perfusions were, O_2 consumption, bile flow, plasma hemoglobin, LDH, SGPT, BSP clearance and ^{131}I-rose bengal clearance. O_2 consumption in the homologous perfusions was about twice that in the heterologous perfusions total bile vol. in homologous perfusion was 2.4 times that in heterologous perfusion after 3 hr Hemolysis was 8 times greater in the heterologo perfusions, SGPT increased 2.5 times and LDH 1. times. BSP clearance was equally poor, amounti to only 40% in 120 min. ^{131}I-Rose bengal clearance in the homologous perfusions at the end of 3 hr. was 2.67 times that in the heterol ogous perfusions. Although function is maintained in hog liver with heterologous perfusion the activity of the parameters studied is generally less for normal and more for abnormal functions.

9456 UMBILICO-PORTOGRAPHY. (Fr.) Kapandj M. (Hotel-Dieu, Paris). Sem. Hop. Paris 43(23):1548-1559, 1967.

After reviewing the technic, literature, and personal experience with regard to the Carbalha method of portography through the umbilical vei the author describes his modifications in which intrahepatic portography by the umbilical vein was performed surgically by inj. of contrast medium into the round ligament of the liver (approx. 15 cases) or nonsurgically during laparoscopy (48 cases). Several illustrative cases are described. With the surgical method of inj. into the round ligament, visualization of the left paramedial vein and its branches in Segments III and IV was possible in the first attempt, while dilatation of the left lateral vein in Segment II and venous abnormalities in Segments IV, V, and VIII were observed in another case. The nonsurgical method combined laparoscopy (which permitted visualization and photography of the liver and other organs of th abdominal cavity) with portography through the

ɔilical vein. This method has also shown that
eumoperitoneum increases the visibility of the
und ligament and the intrahepatic portal
essure without affecting the suprahepatic veins.
:h this method, the author was able to observe
lecrease in portal vein pressure and an increase
the caliber and number of ramifications of
intrahepatic veins following direct portal
. of procaine, and other local anesthetics or
odilators. A diagnosis of Cruveilhier-
ımgarten syndrome was possible with this method
a 52-yr.-old man with enlarged liver and
btful liver function test response. In 2 male
ients (59 and 36 yr. old) with metastatic
cer of the liver, an unusual syndrome consist-
of an association of intrahepatic portal
ertension and numerous anastomoses between
portal and hepatic veins was observed with
s method. The author believes that his method
portography through the umbilical vein, non-
gical and performed under local anesthesia,
sents many advantages.

7 DETERMINATION OF SERUM ORNITHINE-
CARBAMYL-TRANSFERASE BY MICROTITRIMETRY.
.) Counitchansky-Cille, Y., J. F. Bolot and
Creyssel. Rev. Franc. Etud. Clin. Biol. 12(3):
-300, 1967.

test developed by the authors made use of 3
parations: (1) 1 ml of serum was mixed with
l of citruline substrate soln.; (2) 1 ml of
um was mixed with 1 ml of arseniate buffer; (3)
l of citrulline substrate soln. was mixed with
l of arseniate buffer. These preparations
e incubated at 37°C for 24 hr., after which
y were centrifuged. Aliquots of the clear
ernatants were placed in Conway diffusion
ls following incubation for 1 hr. with
chloric acid at 37°C. Ammonia was displaced
an alkaline reagent and trapped in 2 x 10^{-4}
onium chloride which was then back-titrated
ng a Conway microburet. The ammonia liberated
m Preparation 2, the serum blank and from
paration 3, the citrulline blank was sub-
cted from the total ammonia in Preparation 1
lding the ammonia released by the enzyme.
ivity was reported as µg of ammonia nitrogen
0.5 ml of serum. Tests done on the sera of
normal gave a value of 0.019 µg of ammonia
rogen for 0.5 ml of serum. All tests were
e in duplicate. Reproducibility and sensi-
ity of the method were high.

8 SULFOBROMOPHTHALEIN BLOOD CLEARANCE
TEST. PROBLEMS OF INTERPRETATION AND
THER MEANS OF EXPRESSING RESULTS. (Fr.)
let, J. (U. Paris, France) and G. Albot.
h. Franc. Mal. Appar. Dig. 55(11):999-1014,
6.

clearance was studied in a patient with stones
the bile duct. The amount of dye present in
serum at zero time of the test was 100 mg/liter
um; samples of serum were obtained at 8, 15,
75, 90 and 120 min. When plotted, the curve
ibited 2 slopes. During the first 20 min., dye conc. decreased 55 mg/liter of serum or at the av. rate of 2.75 mg/liter of serum/min. In the next 100 min. the dye conc. fell 18 mg/liter of serum, or at the av. rate of 0.18 mg/liter of serum/min. or only about 7% of the former rate. In the first 20-min. period 2.75 mg of dye were removed from the serum/min. representing all the dye in 27.50 ml of serum; therefore the clearance of BSP in this period was 27.5 ml/min. Similarly the clearance in the second period was 1.8 ml of serum/min. The relationships of these 2 slopes, P_1 and P_2, to each other are considered to yield information as to the type of hepatic disease suffered by the patient. After a number of manipulations of the graphs the authors obtained the natural logarithms of P_1 and P_2. At this point it was stated that P_1 and P_2 were already common logarithms and in order to convert to natural logarithms, these were multiplied by the factor 2.3. The value given for P_2 was 0.0013 (the common logarithm of the number 0.997); 0.0013 multiplied by 2.3 equals 0.003 or 0.3/100, designated as K_2 and called a "clearance." With values for K_1 on the ordinate and K_2 on the abscissa of a graph having areas allotted to specific liver disorders, it is believed possible to diagnose a liver defect by the area in which the intercept falls. This diagram, marked with very definite diagnostic zones, is termed the correlation diagram.

9459 SERUM AND BILIARY METABOLITES OF B.S.P. IN RELATION TO THE CURVE OF DECREMENT OF SERUM B.S.P. IN NORMAL SUBJECTS AND SUBJECTS WITH HEPATOBILIARY DISORDERS. (It.) Molino, G. P. (U. Turin, Italy), A. Cravario and E. Giangrandi. Fegato 12(4):409-432, 1966.

In the course of retention and clearance tests employing 5% tetrasulfobromophthalein (5 mg/kg single i.p. dose with blood samples derived 3, 6, 10, 30 and 60 min. after inj.), the non-metabolized dye and 1-3 "slower" serum fractions were separated by chromatography on silica gel. No "slower" fractions were demonstrable at any time in the sera of 5 healthy subjects or in that of a patient with thalassemia. However, such "slower" serum fractions of BSP were found within 10-15 min. (i.e., at the time when the rate of serum decrement of total BSP changes abruptly) in 8 of 9 patients with hepatic cirrhosis, 2 of 2 with acute viral hepatitis, 0 of 3 with viral hepatitis in a stage of regression, 3 of 3 with cholecystitis, 2 of 3 with hemochromatosis, 2 of 2 with obstructive jaundice and 1 of 1 with hemolytic jaundice. They were also demonstrable, after approx. 30 min., in the bile of 2 patients who had undergone cholecystectomy and Kehr drainage a few days before the test was admin. When human serum was incubated for 12-50 hr. with a 0.1% soln. BSP in distilled water (0.1 ml/ml serum), slow fractions were demonstrable in the serum of 2 of 4 healthy subjects, 2 of 2 with acute viral hepatitis, 1 of 2 with viral hepatitis in a state of regression, 7 of 8 with cirrhosis of the liver, 2 of 2 with cholangitis, 1 of 2 with obstructive jaundice secondary to pancreatic cancer and 1 case, each, of cholecystic empyema and cholelithiasis. They were also demonstrable in the sera of 2 patients with apparently normal liver function (1 with thrombosis of the splenic vein, 1 with myocardial infarct) but not in that of 10 other patients with apparently normal liver function in the presence of a wide range of other disorders. They were also demonstrable when BSP was incubated with homogenates of rat liver, kidney or muscle tissue at 37°C, but not when incubation was carried out at room temperature or at -20°C.

9460 HEPATIC CLEARANCE OF B.S.P. ADMINISTERED IN SMALL DOSES TO SUBJECTS WITH HEPATO-BILIARY DISEASES.

(It.) Cravario, A. (U. Turin, Italy), G. Molino and E. Giangrandi. Minerva Gastroent. 12(4):135-141, 1966.

A modified BSP-retention test is described in which 20 mg tetra-BSP was inj. i.v., prior to taking blood samples at 2-min. intervals from the third to the eleventh min., inclusive. Among 20 healthy, adult subjects (10 men, 10 women), the median clearance value (ml/min./kg) was 10.7±1.1 (range = 9.0-13.7); among 10 patients with decompensated Laennec's cirrhosis of the liver, it was 2.5±1.0 (range = 1.3-4.4); among 9 with the same disorder in compensated form, it was 4.3±1.2 (range = 1.9-6.1); among 4 with primary biliary cirrhosis, it was 4.8 (range = 1.1-9.0); among 9 with acute viral hepatitis, it was 3.1±1.0 (range = 1.9-4.5); among 11 with viral hepatitis in the recovery stage, it was 7.4±1.6 (range = 4.8-10.2); among 9 with occlusive jaundice, it was 3.66 (range = 0.8-8.5); among 6 with hemolytic jaundice, it was 14.5±1.5 (range = 11.1-19.5). Among 2 patients with essential splenomegaly, it was 19.0 and 17.4, resp., but fell within essentially normal limits among 6 in whom splenomegaly was secondary to systemic malignancy or thrombophlebitis. In a patient with Rotor's jaundice, it was extremely low (1.7), as it was in a patient with constrictive pericarditis prior to surgery (2.8, as compared to 6.7 after pericardiectomy). Relatively low values (4.7-6.9) were also seen in 2 patients with cardiac decompensation, 1 with myeloma + hepatomegaly and 1 with incipient hemochromatosis. It is concluded that the method is more sensitive than the conventional one, and offers more accurate evaluation of functional liver damage, depending as it does on the factor of hepatic flow. The logarithmic methods employed for calculating both the clearance fraction and the plasma clearance values referred to above are detailed at length.

9461 STANDARDIZATION OF THE BROMSULPHALEIN TEST WITH RESPECT TO BODY COMPOSITION.

(E.) Brohult, J. (Danderyds Hosp., Sweden). Scand. J. Clin. Lab. Invest. 19(1):67-71, 1967.

A procedure is described for calculating the dose of BSP so that the quantity admin. gives an initial level with a narrower spread than when the dose is given per kg body wt.; the procedure involves dosage in relation to the fat-free soft tissue, estimated by an anthropometric method. Two groups of chronic alcoholics consisting of 29 men each were studied; the subjects were fasted overnight. In the first group, BSP doses were related to body wt. (5 mg/kg) and in the second they were related to the estimated wt. of the fat-free soft tissue, the amount inj. calculated from the formula $C\cdot(0.8\,L + \frac{W-L}{3})$ mg, where L is the lean body mass in kg and the coefficient 0.8 is derived from the fact that bone comprises 20% of this; lean body mass was calculated according to an anthropometric method. W is the body wt. in kg, so that W-L is the adipose tissue; this expression is divided by 3, since the fat-free part of the adipose tissue (cell residue and extracellular water) amounts to approx. one-third. The constant C in the formula was set at 7, since this value empirically gave the same av. zero-time conc. for both dosing methods. In addition, both methods were performed on a group of normal subjects (15 men, 17 women). Both groups (normals and alcoholics) showed a significantly narrower spread of the initial values when the dose was calculated from the estimated wt. of the fat-free soft tissue. The usefulness of this new procedure in clinical practice is discussed.

9462 A COMPARATIVE STUDY OF JIRGL'S TEST, ILCA'S TEST AND SIDEREMIA IN A GROUP OF JAUNDICED PATIENTS.

(It.) Nuti, M. (U. Rome) G. C. Leoni and E. Messeri. Minerva Med. 58(18) 692-696, 1967.

Jirgl's Test, said to be positive only in the presence of cholestasis, with the intensity of the reaction directly proportional to the degree of obstruction, is also said to depend on the presence of an abnormal serum mucoprotein reacting with KOH and then, successively, with sulfosalicylic acid, phosphotungstic acid in HCl and anhydrous sodium carbonate with Folin-Ciocalteau's reagent. Ilca's Test, which depends on the degree of turbidity resulting from saturation of serum transferrin with a soln. of ferric citrate and ammonia, is said to yield positive reactions directly proportional to the degree of hepatic damage, but remains negative in the presence of cholestasis, as such. Among 36 patients with viral hepatitis, Ilca's Test was positive in 94.4%, Jirgl's Test was negative in 91.6%. Among 20 with cholestatic jaundice, Ilca was negative in 76.9%, Jirgl was positive in 57.6%. Among 65 with cirrhosis of the liver and 16 with chronic hepatitis, Ilca was positive and Jirgl was negative in all cases. Ilca was positive and Jirgl was negative in 10 of 15 cases of hepatic cancer; both were positive in 3 of 15; Jirgl was positive and Ilca was negative in 1 of 15; both were negative in 1 of 15. Ilca was negative and Jirgl was positive in 4 of 14 cases of cholangitis; Ilca was positive and Jirgl was negative in 4 of 14; both were

e in 2 of 14; both were negative in 4 of
e percentage of false positive or false
e responses yielded by Ilca was tabulated
otal of 8 cases of prehepatic, 61 of
and 26 of posthepatic jaundice as 0%,
d 23%, resp. Comparable tabulations for
re 0%, 4.9% and 42.3%, resp. In all
of patients, determinations of sideremia
results which were too variable to aid
erential diagnosis.

JIRGL'S TEST FOR THE DIFFERENTIAL
DIAGNOSIS OF JAUNDICE. (Ger.) Zach,
y Hosp., Cologne-Merheim, Germany), K.
ann and J. Hemelt. Gastroenterologia
106(6):313-324, 1966.

iations encountered in the Jirgl serum
r the differential diagnosis of jaundice
d a re-examination using his method.
in and seromucoid values were determined
llel. The reagents for the Jirgl test
epared with special care and the test
ly performed. This was also true for the
nation of seromucoids which are essential
Jirgl test; seromucoids were determined
ometry. Bilirubin in serum was measured
Jendrassik method. Additional tests were
ata, Weltmann coagulation band, thymol
tion, alkaline phosphatase, SGOT, SGPT,
. The investigations were carried out on
ents; 21 of whom had obstructive jaundice
tumor or stone; 38 had jaundice of other
and 26 had different disorders without
e. Of 21 patients with obstructive jaun-
6 (76.2%) were positive according to the
est and 5 (23.8%) were negative. Of the
8 with various forms of jaundice, 27
were negative and 11 cases showed a
e Jirgl reaction. The 26 nonjaundice
ere all negative. Bile of 4 additional
s obtained during or shortly after
on proved to be negative. Analyses of
ositive and false negative cases led to
tative conclusion that the Jirgl test is
y based upon a mechanical closure of the
ducts but can become positive when there
ntrahepatic cholestasis. According to
own accounts the test is not dependent
e mechanical obstruction of the biliary
ways only. The mechanism of the reaction
l unknown. It has been suggested that in
asis a physiologically active substance
ased into the blood; such a substance has
n found in man. In the investigations
d in this paper, the bile always was
e when the serum was positive. If this
est is negative an obstruction is most
y but a positive result does not
ntiate extrahepatic from intrahepatic
asis. The seromucoid conc. and the test
showed a poor correlation.

FATTY ACID COMPOSITION OF HUMAN HEPATIC
TISSUE IN MECHANICAL JAUNDICE. (It.)
Salvioli, G. (U. Modena, Italy), L. Marani, G. Vecchi and P. Ferrari. Fegato 12(4):468-477, 1966.

Fatty acid composition was determined by gas chromatography separation of lipid fractions of hepatic tissue in 5 normal subjects (3 women and 2 men; age 25-71 yr.) and 4 patients (3 women and 1 man; age 57-75 yr.) with mechanical jaundice due to gallbladder cancer (1) or gallstones (3). Cholesterol ester separation revealed an increased ratio of short chain fatty acids in jaundiced patients, with a decrease in oleic acid (av. 34.5%) as compared to normal subjects (av. 39.02%). Triglyceride separation revealed a decrease in arachidonic (av. 1.63%; normal av. 5.41%) and linoleic (av. 16.14%; normal av. 21.28%) acids along with an increase in saturated (av. 25.27%; normal av. 21.3%) and monounsaturated (av. 35.66%; normal av. 33.67%) acids. Phospholipid separation revealed a decrease in saturated acids (av. 19.1 and 18.45%; normal av. 22.64 and 19.97%) and a slight increase in oleic acid (av. 17.85%; normal av. 14.64%). Results are difficult to evaluate in view of the changes in fatty acid composition caused by disturbances of intestinal absorption and bile excretion as well as concomitant lesions of the hepatic parenchyma. In general, a decrease in oleic acid among hepatic cholesterol esters indicates defective cholesterol absorption, whereas a decrease in the amount of linoleic and arachidonic acids indicates hepatocellular damage.

9465 HISTOCHEMICAL, CHEMICAL AND SPECTROGRAPHIC STUDY OF HEPATIC PIGMENT IN DUBIN-JOHNSON DISEASE. (Fr.) Chevrel, M. L., B. Ferrand, J. Kerisit and L. Kerisit. Arch. Anat. Path. (Paris) 14(4):260-263, 1966.

Preliminary histochemical studies of intrahepatic pigment obtained from 4 patients with Dubin-Johnson's disease failed to establish a melanic nature of the pigment, although this was strongly suspected because its reaction to the Gomori, Lillie, and Hueck stains and to oxidizing agents differed from that of lipofuscin. A powder was then extracted from 60 g of hepatic tissue obtained at autopsy and freeze-dried according to the Wegman-Rangier technic. Microanalytic studies of the powder were then undertaken and the percentages of C, H, and N were similar to those obtained with a powder prepared from bovine eye; the H content was slightly higher than that reported by Nicolaus (using melanin obtained from melanomas) but other values agreed with those of Masuda (using urinary pigment from patients with Dubin-Johnson's disease). Infrared spectrum studies of the powder showed typical OH or NH group absorption around 3 microns, carbonyl group absorption around 6 microns, and an absorption band around 1625 cm^{-1}. These results are similar to those obtained with melanin obtained from bovine eye and to those reported by other authors. Findings, therefore, seem to indicate that the intrahepatic pigment obtained from patients with Dubin-Johnson's disease belongs to the melanins.

9466 RECURRENT JAUNDICE IN PREGNANCY. II. A STUDY OF THE ESTROGENS AND THEIR CONJUGATION IN LATE PREGNANCY. (E.) Adlercreutz, H. (U. Helsinki Meilahti Hosp.), A. Svanborg and Å. Ånberg. *Amer. J. Med.* 42(3):341-347, 1967.

In 7 women (22-30 yr. old) with recurrent jaundice of pregnancy, urine samples for hormone analysis were taken on 17 occasions during the last trimester, when jaundice was present for at least 2 wk. Simultaneous sample of urine, blood and bile were taken in 1 (23 yr.) who had recurrent jaundice during 4 successive pregnancies. Results were compared with 16 urinalyses from 11, 7 blood analyses from 7, and 10 bile analyses from 10 healthy pregnant women. For blood analysis, 30-50 ml was withdrawn from the antecubital vein; for bile analysis, 30-50 ml by duodenal intubation (Adlercreutz). The following were measured: estriol, estrone, estradiol-17B in urine; these 3 in sulfate and glucosiduronate fractions of bile and blood; 3-monosulfates of the 3 in urine. Conjugation patterns of estrogens were studied by dividing conjugates into 2 groups by Sephadex 25 gel filtration (peaks, I, II of Beling). Urinary excretion of the 3 was normal during the jaundice phase. In these patients, 17B-estradiol-3-sulfate was decreased, estriol-3-sulfate increased. There was a shift from Peak I to Peak II conjugates following gel filtration of urine samples. Peak II conjugates contained significantly more of 1 or several unknown polar estrogens other than estriol. In the patient studied for urine, blood and bile, estrogen conc. in all 3 was decreased. The proportion of 3-monosulfates was higher than in normals. These observed significant changes in estrogen metabolism are thought to be secondary to jaundice and impaired enterohepatic circulation of estrogens, and not a primary defect bearing a causal relationship to the liver disease.

9467 THE MECHANISMS OF IDIOPATHIC CHRONIC JAUNDICE. (Fr.) Magnenat, P. (U. Lausanne, Switzerland), F. Minio and A. Gautier. *Bull. Soc. Med. Hop. Paris* 118(1):65-74, 1967.

Six cases of Gilbert's, 5 Dubin-Johnson's, and 2 Rotor's syndrome; all were studied by electron microscopy as was Criglar-Najjar's. Distinguishing features, sufficient to differentiate the 4 forms, were found. The disorder described by Israels is very rare; the principal anomaly is the formation of bilirubin by precursors of hemoglobin, proved by radioactive glycine which appears in fecal stercobilinogen without incorporation in the hemoglobin of RBC. The Criglar-Najjar disorder is marked by neonatal jaundice, often accompanied by severe encephalopathy, due to a hereditary deficiency of glucuronyl-transferase activity and, therefore, of glucuroconjugation of bilirubin; defective glucuroconjugation is proved by the urinary excretion of such substances as unconjugated menthol and *in vitro* by the biochemistry of biopsy tissue. Gilbert's jaundice is distinguished by a parti deficiency of glucuronyl-transferase activity and a defective retention of bilirubin in the hepatocytes. The Dubin-Johnson syndrome shows retention of a pigment of unknown composition (lipochrome?) with a persistent hyperbilirubin and a normal glucuro-conjugation. Rotor's jaundice is positive for the direct Van den Be reaction; there is an absence of pigment in th liver cells; and a tendency to opacity of the biliary ducts. Five different characteristics appear in different combinations in 4 of these forms of jaundice under the electron microscop (1) lesions of the vascular pole, (2) pigment inclusions, (3) tendency for fibrillar degener tion of mitochondria, (4) tendency for vascula degeneration of mitochondria, (5) biliary stas within hepatocytes. Criglar-Najjar's jaundice has (1) and (5). Gilbert's has (1), (2), and (3). Dubin-Johnson's, (1),(2),(3),(4) and (5) and Rotor's (1),(2),(3), and (5).

9468 PHYSIOPATHOLOGY OF JAUNDICE OF FATTY LIVER. (Fr.) Pavel, I. (Nutr. Clin Bucharest), S. Câmpeanu, N. Ş. Chisiu, H. Bonaparte, A. Petrovici and M. Stoian. *Rev. Roum. Med. Intern.* 4(1):27-34, 1967.

Three cases of fatty liver were studied clinically, by means of function tests, and by ultramicroscopy; the cases were of different grade, with a diabetic background but without any other known etiologic factor; 1 patient ha lipotrophic diabetes; the fatty liver depositi was mild in 1, medium in another and massive i the third. All presented a clinical picture o isolated, enlarged liver. Serum protein chang approaching the extreme limits of the normal range occurred in the first 2. The BSP test was 6 and 9.2% in the first 2; clearance of endogenous bilirubin was +35% and +30% (normal +45%). These tests were not applied to the third patient because of extreme lipemia. Jaundice appeared in the third case as a resul of admin. of an anabolic steroid. Jaundice lasted for several days after cessation of tre ment. The chief ultramicroscopic changes from normal were: (1) Thickening of the cell membrane, dilatation of the bile canaliculi in certain zones; reduction in number of microvil in some regions. (2) Numerous cytoplasmic vacuoles, some filled with lipid material and some finely granular (glycogen); ribosomes wer present at the outer edge of these vacuoles. (3) Mitochondria appeared normal but some show ballooning with destruction of cristae. (4) Nuclei appeared normal. (5) The sinusoids wer full of osmophilic granular material and debri of cellular organelles; apparently the massive amounts of lipids on their way to the blood caused extensive cellular damage. In over 30 cases of fatty liver no spontaneous case of

e has been noted. Fatty liver induced in
bit by feeding 12-15 g of vegetable oil
terial rich in cholesterol and inorganic
d in a fatal jaundice. Laboratory tests
peded. Some details were different but,
main, the same general picture emerged
e ultramicroscopic examination. The
e produced in the rabbit may arise from
g of biliary passageways, and/or massive
tion of hepatocytes.

CATECHOLAMINE LEVELS IN PORTAL, HEPATIC,
AND SYSTEMIC VENOUS BLOOD IN PORTAL
NSION. (E.) Joly, J. G. (U. Montreal,
, J. Leduc, J. Bernier, P. Lavoie and
let. Lancet 2(7507):121-123, 1967.

patients in this study were divided into
s. Group 1 was composed of 11 patients
postsinusoidal type of portal hypertension;
irrhosis, 7 of which were alcoholic
is and 2 cirrhosis of unknown etiology; 1
had gastric carcinoma with extrahepatic
obstruction without liver metastases, and
etastatic growth in the liver. Group 2
ed of 5 patients without portal hyper-
; 3 had healed alcoholic hepatitis, 1 had
artery thrombosis with liver infarcts
ad chronic relapsing pancreatitis. Com-
epatic and umbilicoportal venous catheteri-
was used to sample blood in the vena cava,
atic vein and the portal vein; catechol-
evels were determined by means of a
etric method. No difference in epinephrine
epinephrine plasma levels was found in
roups. Mean portal venous plasma levels
pinephrine were higher than mean hepatic
plasma levels, suggesting that the liver
izes circulating norepinephrine. It is
ed that catecholamine plasma levels have
ing on portal hypertension.

DYNAMIC OBSERVATION OF THE PORTAL
CIRCULATION PRIOR TO AND AFTER OMENTO-
IAPHRAGMOPEXY IN PATIENTS WITH PORTAL
NSION. (Rus.) Ender, L. A. (Moscow Reg.
s. Clin. Inst.). Vestn. Khir. Grekov.
3-20, 1967.

atients with liver cirrhosis and intra-
blockade of portal circulation after
epatodiaphragmopexy, 10 had high (390-420
and 16 low-moderate (220-380 mm) portal
nsion. Of 10 with high portal hyper-
, 7 died immediately or within 1.5 yr.
urgery, while 1 of 2 who remained alive
fuse hemorrhage 14 mo. after surgery and
operated on. Only 1 patient had no
age at any time; when observed 5 yr. and
ater, the intrasplenic pressure was
ed (from 400-520 mm) and the spleen was
y enlarged. Within 1.5 yr. the other
s developed irreversible decompensation
portal circulation and died from profuse
ogastric hemorrhages. Two of 16 with low-moderate portal hypertension died within one yr. after surgery (1 from hemorrhage, 1 from hepatic insufficiency), while 14 were observed, because of the need for repeat surgery, for 8 mo.-5 yr., 2 mo. after surgery. Increase of intrasplenic pressure from 40-340 mm was observed in 11, being max. in those patients with low portal hypertension. The development of natural portacaval anastomoses after surgery was noted in 5 subjects, and significant splenomegaly developed in 9; 5 patients with low-moderate portal hypertension developed ascites immediately after surgery, while 6 developed esophageal-gastric hemorrhages at various times after operation. After surgery the portal circulation improved in only 1 of 26. Thus, the majority of patients had exacerbation of the portal circulation and an increase of portal pressure after omentohepatopexy. In patients with portal hypertension who were not treated surgically, the intrasplenic pressure exhibited no changes. A comparative study of splenoportogram before and after omentodiaphragmopexy, studied in 16 patients, showed changes upon second observation in 8 cases; an increased number and diameter of collaterals was found in 7, impaired intrahepatic vascular diagram in 5, and increase of the diameter of the portal vein in 2, and thrombosis of the portal vein in 2 patients with low portal hypertension. Two case histories are presented in some detail.

9471 SIGNIFICANCE OF RADIOMETRIC METHOD OF STUDY OF CARDIOPORTAL BLOOD CIRCULATION IN PATIENTS WITH CHRONIC DISEASES OF THE LIVER. (Rus.) Bondar, Z. A. (First Moscow Sechenov Med. Inst.) and T. F. Novikova. Klin. Med. (Moskva) 45(3):26-32, 1967.

The method consisted of i.v. admin. of ^{131}I-labeled albumin (0.3 μc/kg) into the cubital vein and blockade of the thyroid gland for 3 days with a 3% soln. of KI. This study was performed on 47 patients (38 men, 9 women; 19-65 yr. old) with chronic diffuse diseases of the liver. The time of cardioportal blood circulation in portal, postnecrotic or biliary liver cirrhosis (30) was 41.2, 42.5 and 36.5 sec.; in chronic hepatitis (9) it was 29.6 sec.; in fatty liver (4), 24.8 sec.; in benign hyper-bilirubinemia (4), 25.5 sec.; and in healthy normals it fluctuated between 19-30 sec. There was a significant difference in the indices of vascularization in patients with liver cirrhosis (av. 940 impulses/sec.) and chronic hepatitis (av. 1014 impulses/sec.). Blood clearance was significantly delayed in patients with liver cirrhosis. Cardioportal circulation time was increased in 11 of 12 patients with ascites and collateral blood circulation; in all patients with cirrhosis and splenomegaly, the cardioportal circulation time was delayed in proportion to the degree of splenomegaly. In 6 patients with cirrhosis but no portal hypertension, the cardioportal circulation time was prolonged (33-52 sec.); this is of diagnostic significance. A direct relationship between the level of intrasplenic pressure and cardioportal circulation time was noted. Thus, the radioisotope method of determination of cardioportal circulation time could be used both for diagnosis of pronounced portal hypertension and study of its initial forms. In 11 patients in the active stage of hepatic cirrhosis and in 15 patients with the inactive stage of cirrhosis, the cardioportal circulation time was 45 and 37.6 sec., resp. Therefore, a delay in the cardioportal circulation with a corresponding clinical picture can be indicative of exacerbation of the pathological process. In 2 patients with chronic hepatitis, unchanged liver function tests, increased weakness, subcostal pain and liver pain upon palpation, the cardioportal circulation time was prolonged (44 and 45 sec., resp.). Thus, hemodynamic disturbances of hepatoportal blood circulation are one of the early symptoms diagnostic of the active process of chronic hepatitis and liver cirrhosis.

9472 STUDY OF BIOGENIC AMINE TITER IN PORTAL HYPERTENSION IN EXPERIMENTAL AND CLINICAL CONDITIONS. (Rus.) Gorbatenko, V. P. (State Therap. Clin., Cent. Res. Lab., Moscow), A. S. Chechulin, V. V. Menshikov, T. D. Bolshakova, L. S. Bassalik and T. I. Lukicheva. Ter. Arkh. 39(1):66-72, 1967.

Portal hypertension was induced by incomplete ligation of the portal vein in 5 completely-operated dogs, with s.c. exposure of the spleen. After ligation of the portal vein (25% of the lumen remained open), the pressure (in mm H_2O) increased from 65-90 to 140-180. During portal hypertension the amount of pressor amines (serotonin, catecholamines and their metabolites and 5-hydroxyindole acetic acid) and their metabolites increased. Three dogs which had repeated surgery at the end of the chronic experiment (3-7 mo. of observation) exhibited an even greater increase in pressure (218-300 mm H_2O) than after their initial operation. The admin. of serotonin (0.1 mg/kg), epinephrine (1 ml of 0.1% soln.) and norepinephrine (1 ml of 0.2% soln.) into the portal vein produced an increase in pressure, even after the use of depressants; pressure with serotonin did not reach the initial level, but pressures with the remaining 2 agents exceeded the initial level. Pressor action was brief; it was highest with norepinephrine and lowest with serotonin. Reserpine also displayed depressant action after admin. of pressor amines. A clinical study made on 9 patients with chronic hepatitis and 19 with liver cirrhosis (compensated in 5, decompensated in 14, ascites in 5, chronic portal vein thrombosis in 3, gastrointestinal hemorrhage in 5, liver insufficiency in 11, exacerbation of hepatitis or cholangitis in 10) revealed a tendency toward an increase in the content of pressor amines and their metabolites. In 20 of 28 patients intrasplenic pressure (measured by splenoportography with splenomanometry) av. 73.3 mm in chronic hepatitis, 302 and 374.5 mm, resp., in compensated and decompensated cirrhosis. Blood serotonin, determined by a biological method, and the daily content of catecholamines and metabolites of pressor amin in the urine, showed a tendency to increase in the patients with chronic hepatitis and liver cirrhosis, especially in the case of decompens cirrhosis. The excretion of vanillyl-amygdali homovanillic and 5-hydroxyindole acetic acid w increased in patients, especially those with h titis. The content of pressor amines was chang more sharply than that of their metabolites. possibility of an aggravating action of presso amines on the course of hepatic cirrhosis is n excluded. The rapid and increased pressor eff by periodic accumulation in the portal bed, to er with other factors, could cause hemorrhage collateral circulation. Arterial hypertension angina pectoris apparently developed under the action of biogenic amines in those patients wi liver cirrhosis.

9473 REGULATION OF THE BLOOD AND INSULIN- LEVELS OF HUMAN SERUM BEFORE AND AFT PORTACAVAL SHUNT. (Fr.) Azerad, E. (Beaujon Hosp., Clichy, France), J. Lubetzki, J. Duprey and D. Friedler. Diabete 15(1):50-56, 1967.

Subjects (10 men and 10 women) with portal hypertension were studied with respect to gluc tolerance and glucose metabolism before and after portacaval anastomosis; none had a histo of diabetes; 18 underwent a portacaval end-to- anastomosis, 1 a splenorenal anastomosis, and a portacaval side-to-side anastomosis; 15 had alcoholic cirrhosis, 4 cirrhosis of unknown origin and 1 congenital liver fibrosis; the ag span was from 23 yr. (congenital fibrosis of t liver) to 69 yr. (alcoholic cirrhosis). The first test was given 1-18 days before and the second test 8-19 days after the operation; the dosages varied somewhat depending upon the met of analysis (reduction or enzymatic) but were the range of 0.33 g/kg body wt. in the form of a 50% soln. of glucose inj. i.v. The coeffici of glucose assimilation (K) varied for the 20 patients between 0.75×10^{-2} and 2.94×10^{-2}. Coefficients where K is greater than 1.30 x 1 are considered normal and where K is less than 1.00×10^{-2} the coefficients indicate diabetic types; intermediate values for K are of doubtf significance. Before operation the range for the patients was 0.75×10^{-2} and 2.94×10^{-2}; within normal limits, 10 were of diabetic type and 4 were doubtful. After operation the rang was from 0.48×10^{-2} to 3.54×10^{-2}; 5 were in normal range, 6 of diabetic type and 9 doubtfu Blood insulin conc. was measured in 12 subject before and after operation: the range before from 2-110 µU/ml with an av. of 23 µU/ml and f 0-50 with an av. of 20 µU/ml. As the surgical procedure did not significantly alter the resu of the preoperative tests, the new hemodynamic conditions did not determine the onset of post shunt diabetes which has been reported by othe Different physiological mechanisms may explain these facts.

VENOUS THROMBOSIS AND MANOMETRIC
STUDIES IN PORTAL HYPERTENSION DUE TO
EPATIC BLOCKADE. (Fr.) Leger, L. (Cochin
Paris), R. Abelanet, G. Lemaigre and R.
mot. Presse Med. 75(4):177-182, 1967.

uses of portal hypertension are systemetized
general types: (1) Presinusoidal blocking:
hypertension due to compression or obstruc-
f intrahepatic branches of the portal vein
s occur in schistosomiasis, essential hepatic
ension and biliary fibroadenomatosis. In
osomiasis, inflammatory granulomatosis is
followed by thrombophlebitis, recanalization
thrombus, always with increased resistance
od flow, in branches of the portal vein and
mes in the portal vein itself. Occasionally
in or veins may be completely and perma-
blocked; portal pressure is elevated and
leen enlarged (sometimes to twice normal
pressure in the hepatic veins is normal.
ential hypertension of the liver, portal
re is high with no evident cause; the 1
te factor known in essential hepatic hyper-
n is the inelasticity in the entire or
f the portal bed. Biliary fibroadenomatosis
ked by biliary cysts and extensive biliary
roliferation, dense sclerosis of parenchyma,
rtal fibrosis, all contributing to in-
d portal pressure. (2) Postsinusoidal
ng: portal hypertension due to obstruc-
f hepatic veins is most often seen in
c cirrhosis; obliterating fibrosis of the
c veins causes ascites; the arterial system
mal; despite many structural modifications
branches of the portal vein, such as
ement of the lumen, no thrombosis has ever
oted; the venules become encased in a com-
f elastic fibers conferring a ridigity
his part of the system; 75% of cases show
oses in branches of the hepatic veins.
al management has been by splenectomy,
er of splenic venous flow to the renal
and portacaval anastomoses according to
quirements of the individual case. Blood
re was measured in the portal vein and in
patic vein; pressure was reduced from 24
hepatic vein to 10 mm Hg in 1 instance.
epatic portal pressures were usually about
Hg reduced by operation to 10 mm Hg or less.

OBSERVATIONS ON SHOCK PRODUCED BY
ACUTE PORTAL OBSTRUCTION. EXPERIMENTAL
(Gr.) Blatzas, G., P. Andreadis, D.
dakis and C. Tountas. Galenus 9(2):65-73,

portal obstruction was produced in 12 dogs.
of these were inj. with pituitrin (10 mg/kg
t./hr.) prior to the application of portal
ction. Observations on the control animals
a rapid decline in blood pressure and
blood pressure until stabilized to a lower
while the portal venous pressure in-
d to about 90 cm H_2O. Temporary brady-
was also observed after the obstruction was effected. The electrolyte picture was as follows: Serum Na unchanged, serum K increased by 0.5 mEq/liter, and the pH dropped to 6.8 (from 7.3); hemoglobin and hematocrit increased. In the animals inj. with pituitrin there was a fall in the arterial blood pressure which was, however, less rapid than in the control animals, due to the vasoconstricting effect of pituitrin on the mesenteric arterioles. The hemoglobin and hematrocrit were increased due to the pooling effect of blood in the portal circulation; the portal venous pressure was lower than in the control animals and the pH was reduced lower than in the controls due to reduction of blood vol. following reduced catecholamine effect. Pituitrin reduced the degree of shock and increased the survival rate of the dogs following removal of the obstruction. All animals died within approx. 2 hr. after the obstruction was effected, if the latter lasted for more than 22 min. This can be explained by the toxic effects of metabolic byproducts that were not removed adequately from the circulation.

9476 THE EFFECT OF PARTIAL PORTACAVAL TRANSPOSITION ON THE CANINE LIVER. (E.) Marchioro, T. L. (U. Colorado Sch. Med., Denver), K. A. Porter, B. I. Brown, J. B. Otte and T. E. Starzl. Surgery 61(5):723-732, 1967.

Partial portacaval transposition was performed, anastomosing the supra-adrenal inferior vena cava to either the right or left branch of the main portal vein. In the resulting preparation nonhepatic splanchnic venous blood supplied 1 portion of the liver whereas systemic venous blood perfused the remaining portion. Three dogs with right, and 4 dogs with left, transposition were studied for 10-94 days. No clinical abnormalities were seen but both gross and microscopic atrophy were marked as was glycogenolysis in that portion of the liver receiving systemic venous blood. An electromagnetic square wave flowmeter was used in blood flow studies in another 8 dogs. Flow was measured in branches of both right and left portal vein before and from 1 to 4 hr. after partial transposition to either the right, in 4 dogs, or to the left in another 4 dogs. Rates of flow remained unchanged in 5 instances, increased in 11 instances. In another study 2 dogs received a jugular venous autograft between the abdominal aorta and the right or left main portal vein branch. Both atrophy and glycogenolysis in the portion receiving arterial blood were comparable to that described above in liver fractions perfused with systemic venous blood. As a result of these and earlier studies the authors suggest the existence of a hepatotropic substance in splanchnic venous blood.

9477 MESENTERIC-CAVAL ANASTOMOSIS FOR PORTAL DECOMPRESSION. (E.) Zuidema, G. D. (Johns Hopkins U. Sch. Med., Baltimore, Md.) and P. A. Ebert. Johns Hopkins Med. J. 120(4):201-209, 1967.

This technic was used in children (9) and adults (3; previously splenectomized) with extrahepatic block, and provides excellent portal decompression using relatively large vessels. Risk of thrombosis is low, the outlook for prevention of recurrent variceal hemorrhage good. A right paramedian incision is made in the abdomen; the transverse colon elevated superiorly; the small intestine retracted downward. Portal venous pressure is measured in a small mesenteric tributary, and this system is visualized by inj. of 25 ml 50% Hypaque. In extrahepatic block, if the superior mesenteric vein is suitable for anastomosis, it is exposed at the inferior base of the transverse mesocolon near the entrance of the right colic vein, is dissected and a 2-3-inch segment isolated. The right colon is mobilized; the retroperitoneal structures exposed; the inferior vena cava dissected from the level of the renal veins to below both iliac bifurcations; all tributaries ligated and divided to free the entire vessel. A tunnel is made in the mesentery posterior to the superior mesenteric vein so that the divided vena cava can be passed anteriorly. The latter is occluded below the renal veins, and both common iliac veins occluded. The latter are divided below the bifurcation, the distal ends oversewn with arterial sutures. A suture is placed in each corner of the proximal right iliac vein and these sutures are passed through the tunnel, avoiding any tension on the vena cava. When properly placed, the vena cava is divided, the bifurcation discarded. Only rarely (in obesity, low-lying duodenum) must the iliac vein be used for the anastomosis. The superior mesenteric vein is clamped and rotated so that an ellipse may be excised from its posterior wall. Posterior suture line is 5-0 silk continuous over and over everting stich; anterior, interrupted 5-0 silk everting mattress sutures. The right colon is returned to normal position, but not sutured in place. Pressure is measured after completion of shunt, the peritoneum over superior mesenteric vein closed and liver biopsy made. Of 9 children, 7 were successfully operated on. After up to 3 yr., none have experienced subsequent hemorrhage. One adult, who was operated on in an emergency, had postoperative recurrent variceal hemorrhage, requiring transthoracic variceal ligation, and massive edema of lower extremities, but has been well for 2 yr.

9478 EXPERIMENTAL STUDIES OF THE POSSIBILITY OF SHUNTING PORTAL BLOOD THROUGH CHANNELS MADE OF BONE AND CONNECTING THE SPLEEN AND LIVER.

(It.) Rapisarda, L. M. (U. Palermo, Italy) and M. Romano. Minerva Chir. 22(5):232-238, 1967.

In 1 group of dogs, progressive portal hypertension was induced by inserting a cellophane sheath into the portal vein at the level of the hepatic hilus. In a second group, porous bone derived from the rib of the same animal was used to form a permanent connection between the spleen and liver, 120 days before occlusion of the portal vein by means of a tourniquet. In a third group, progressive portal hypertension was induced by a cellophane sheath,
as above, at the same time a similar osseous c
nection between the spleen and liver was const
As compared to the hypertensive controls, both
groups of animals bearing the osseous shunts
achieved a significant degree of decompressio
portal hypertension, due in part to the artifi
shunt and in part to the progressive developme
a network of vascular (and connective-tissue)
neoformations surrounding it.

9479 TECHNIC FOR THE EXTRACORPOREAL CIRCU TION OF THE LIVER ISOLATED IN SITU.

(It.) Benzi, G. (U. Pavia, Italy). Farmaco
[Prat.] 22(5):276-283, 1967.

The method has been used on 22 dogs (11.7-29 k
body wt.) and 4 baboons (wt. 11.4-16.2 kg)
following preanesthesia with urethan and durir
closed circuit anesthesia with nitrous oxide,
cyclopropane, ether, and others. Venous bloo
from the hepatic veins was made to flow throu
a portion of the inferior vena cava. After
proper treatment, oxygenated blood was returne
to the liver through the terminal branches of
the portal vein, since the hepatic artery has
been ligated. In various preliminary experiments, arterial perfusion was attempted by mea
of the hepatic artery itself, after having
ligated the portal vein. No differences were
observed with regard to hepatic behavior with
either technic, although biological and metabolic studies were more easily performed usin
the portal system as the afferent blood suppl
During a perfusion period of 2-4 hr. various
serum determinations were performed on blood
from the extracorporeal hepatic circuit: SGP
sorbital dehydrogenase, and leucine aminopeptidase levels were normal, while SGOT leve
gradually increased with time. The above
technic can be added to the conventional meth
of studying hepatic metabolizing activity
inasmuch as it avoids both direct metabolic
interference with other organs or tissues and
various modifications which in vitro methods
induce in different substrates.

9480 INDICATIONS AND OPERATIVE PROCEDURE FOR PORTOCAVAL ANASTOMOSIS. (E.)

Zenker, R. (Munich U. Sch. Med., Germany) and
H. Hamelmann. J. Cardiov. Surg. 8(2):136-141,
1967.

In a review of 75 of these operative procedure
hepatic failure, and not technical problems, w
responsible for almost all operative fatalitie
An index for determination of operative risk a
postoperative prognosis was formulated after t
clinical coefficient of Leger. The criteria
and their point values are: precoma/coma, 6;
60 yr. or older, 4; recurrent bleedings, 4;
therapy-resistant ascites, 6; transient ascite
3; total bilirubin 1.2-2 mg%, 3 (above 2 mg%,
serum albumin 3 g% or less, 4; prothrombin tim
of 50% or less, 4; Takata of 50 mg% or less, 4
platelet count of 100,000 or less, 2; edema of
extremities, 2. With index less than 12,

val was 93% (25 of 27); at 13-16, survival
50%, with ascites the most common; at 17 or
e, mortality was 90%. In the last group
emergency operations on recurrent bleeding,
py-resistant ascites, and those with low
l protein values. Use of the index in this
reduced the operative mortality from 30%
2% (1 in 16). In cases of ascites, the
nction must be made between parenchymal
position as the cause of ascites and ascites
e result of mechanovascular decompensation.
e latter group, portacaval anastomosis
best results. The authors preferred
inal incision, selected the anastomosis on
asis of anatomical presentation and always
pted side-to-side anastomosis in ascites.

HEMOSTASIS IN HEPATIC SURGERY BY MEANS
OF TEMPORARY OCCLUSION OF THE AFFERENT
VESSELS OF THE LIVER. EXPERIMENTAL STUDY.
De Santis, U. (Sant'Omero Civil Hosp.,
o, Italy). Ann. Ital. Chir. 43(2):349-357,

wing ether anesthesia and aperture of the
en, the afferent blood vessels of the liver
slowly clamped in 15 rabbits of both sexes
ing approx. 2 kg. Five animals (Group 1)
clamped for 10-12 min.; 5 (Group 2) were
ed for 20-22 min., 2 of which were treated
chlortetracycline before and after surgery;
oup 3) were clamped for 20-22 min. under
hermia obtained by peritoneal irrigation
saline cooled to 1°C. Some animals were
ficed 48 hr. after surgery, and histological
es of liver fragments were performed.
ving animals were followed for approx. 1 mo.
ls of Group 1 showed edema and cyanosis of
esentery and intestinal wall which regressed
on as the clamp was removed; microscopic
es revealed normal lobar structure, hepa-
es, and biliary ducts along with slight
nce of vacuolation. Animals of Group 2
d enlarged spleen, marked intestinal
sis, and irreversible hemorrhagic lesions;
animals died within 48-72 hr., except the
ated with chlortetracycline who survived;
vacuolization with fragmentation and dis-
ation of the nucleus and protoplasm was
ved microscopically. All animals of Group 3
ved; histologically, hepatic structure was
rved and no vascular repletion was observed;
cells had a spongy appearance. Results
ate that temporary occlusion of the
ent blood vessels of the liver can be toler-
for periods of approx. 10 min., after which,
ional and anatomical changes of varying
e cause death. Mortality is lowered in
ls in which occlusion lasts more than 10
es if an antibiotic is admin. before and
surgery. Mortality was markedly lessened
imals in which occlusion was performed for
ng as 20 min. under hypothermia.

HETEROLOGOUS LIVER PERFUSION IN ACUTE
HEPATIC FAILURE. (E.) Watts, J. McK.
(Monash U., Victoria, Australia), H. A. F.
Dudley, F. W. Gurr and J. A. Owen. Brit. Med. J.
2(5548):341-345, 1967.

The liver (1-1.2 kg) was removed from a pig (30-40 kg) aseptically. The cystic duct was ligated, and the hepatic artery, portal vein, inferior vena cava and common bile duct were cannulated before the hepatic vascular tree was flushed free of blood with heparinized Ringer's lactate. The patient's arterial blood fed from an indwelling arteriovenous shunt (brachial artery), by means of a heat-exchanger, into the hepatic artery and portal vein of the pig liver, from which venous blood drained by gravity into a venous reservoir and was then pumped back into the patient's cephalic vein. Whole-body and regional heparinization were used in 3 perfusions each. Fluid exuded from the liver surface was collected and its vol. replaced by a continuous infusion of 5% human serum albumin. Bile was collected at 30-min. intervals; flow rate and blood chemistry (including arterial pO_2 and pCO_2) were measured intermittently; liver temperature and blood pH were maintained within physiological limits. Of 3 patients perfused, 1 survived. Septicemia, hypocalcemia, thrombocytopenia, and prolonged prothrombin time occurred in all 3; renal failure and gastrointestinal bleeding in 2; hypoglycemia and status epilepticus in 1 each. In 5 of 6 perfusions, there was a definite lightening of consciousness and increased response to stimulation. The extracorporeal liver extracted ammonia and bilirubin from plasma, secreted bile, and utilized O_2. Flow rate in 2 of 6 perfusions was less than the required 0.5 ml/g liver/min. The required shunt was large, but when it was maintained, acidosis and hypotension did not occur. The 2 perfusions in the surviving patient were of 8 and 9 hr. duration.

9483 BLOOD AMMONIA IN PATIENTS WITH PORTAL HYPERTENSION SYNDROME WHO UNDERGO SHUNT SURGERY. (It.) Santangelo, M. L. (U. Naples, Italy), N. Ricciardelli, E. Triggiani, C. Corsale and E. Antonini. Fegato 12(4): 389-407, 1966.

Elevated blood ammonia was found before surgery in all of 22 patients undergoing shunt operations for portal hypertension secondary to hepatic cirrhosis. The patient group included a boy and a girl aged 11 yr.; two 12-yr.-old boys; 2 boys aged 14 and 15, resp.; 10 men and 6 women, aged 19-62. In all 22, blood ammonia was increased immediately after shunt surgery, rising from a mean of 225-343 μg/ml. In most cases, but not all, it fell within 15 days to approx. preoperative levels (mean = 234 μg/ml). The degree of postoperative increase observed was directly proportional to the width of the shunt. There was no significant correlation between postoperative blood ammonia levels and postoperative encephalopathy. It is concluded that partial shunt operations are probably to be preferred to total ones.

9484 MEASUREMENT OF HEPATIC BLOOD FLOW BY ^{85}Cr IN RATS DURING SHOCK CAUSED BY BLOOD LOSS. (Ger.) Waldeck, F. (Johannes Gutenberg U., Mainz, Germany), H. Hutten and J. Grote. Pflueger. Arch. Ges. Physiol. 294(3): 201-213, 1967.

After inj. of heparin (250-350 g), rats were catheterized (1) in the aorta through a carotid artery and (2) in the portal vein through a mesenteric vein. The arterial catheter was connected by means of a 3-way valve to a Statham strain (pressure) gauge or to a graduated syringe for the withdrawal or reinfusion of blood. The portal catheter ended in a T-tube, 1 limb connected to a chamber containing a strain gauge, the other to a syringe for intraportal inj. Strain gauge voltages amplified and calibrated were recorded as pressures in mm Hg. $^{85}CrCl_3$ in 0.9% NaCl soln. was used as the indicator; each ml contained 0.825 mc; a shock inj. of 0.1-0.15 ml was admin. by the portal vein; radioactivity, reaching a max. of 3.10^3 impulses/min., was detected on the surface of the liver and recorded twice, once as a linear number of impulses/min., the other as a logarithmic function. From the simple logarithmic plot of the half-life curves the rates of blood flow were calculated using one or the other of 2 formulas which yield close results. One of these, $\bar{f} = \lambda \frac{0.693}{T\ 1/2}$ where $\bar{f}$ is the av. flow in ml/g of tissue/min.; λ = 0.987, the partition coefficient of the isotope between blood and tissue and T 1/2 = half life of the isotope = 27 sec. = 0.45 min. when mean arterial pressure = 110 mm Hg. $\bar{f} = 0.987 \frac{0.693}{0.45} = 1.52$ ml/g of tissue/min. As blood pressure decreased from normal, blood flow decreased exponentially. Apparently below an arterial pressure of 60 mm Hg or portal pressures below about 5 mm Hg resistance in the liver increased very rapidly because these pressures were below the critical pressure for the opening of sinusoids.

9485 HEPATIC RHEOGRAM CHANGES IN VARIOUS DISEASES. (Rus.) Tadzhiev, K. T. (Tadzhik Med. Inst., USSR) and G. I. Nosenko. Sovet. Med. 30(2):13-19, 1967.

In 20 healthy adults (20-30 yr. old), the rheographic index fluctuated between 1.1-1.8 (av. 1.5), the systolic rise of the rheogram or Q-B interval was 0.08-0.15 sec. (av. 0.11), duration of the period of quick filling or B-C interval was 0.15-0.21 sec. (av. 0.19), total duration of systolic filling or B-D interval was 0.17-0.30 sec. (av. 0.27), and intrasystolic indicator of filling was 69-75%. Of 67 patients with various diseases, 27 were treated surgically. In 10 patients with atrophic hepatic cirrhosis and ascites (and probably 10 patients with splenomegalic hepatic cirrhosis without ascites), the Q-B interval was 0.09-0.14 sec. (av. 0.11), the rheographic index was 0.2-0.8 (av. 0.4), B-C interval was 0.08-0.18 sec. (av. 0.13) and the intrasystolic indicator of filling was 30-62%. The hepatic rheogram remained unchanged in 2 patients with cancer o
the papilla of Vater and acute obturation of t
common bile duct. In 3 patients with cancer o
the pancreas and in 4 of 7 patients with
cholelithiasis, the B-C interval was 0.09-0.14
sec., intrasystolic indicator or filling was l
than 60% and the rheographic index was 0.7-0.9
In 10 patients with atherosclerosis the rheographic index was 0.8-1.1, the Q-B interval wa
0.11-0.15 sec., the B-C interval was 0.16-0.19
sec. and the intrasystolic indicator of fillin
was 50-65%. In 4 of 5 patients with Pick's
pseudocirrhosis, the Q-B interval was 0.16-0.2
sec., and in 5 of 5 the B-C interval was
shortened and the intrasystolic indicator of
filling was 40-55%. In 20 patients with mitra
valve disease predominantly with stenosis, the
rheographic index was 0.8-1.0, the Q-B interva
was 0.18-0.20 sec., B-C interval was 0.10-0.10
and the intrasystolic indicator of filling was
50-65%.

9486 TREATMENT OF THE BUDD-CHIARI SYNDROM
ANATOMIC AND TECHNICAL BASES FOR A
PORTO-ATRIAL VASCULAR INTERCONNECTION. (Fr.)
Marion, P. and A. Bouchet. Lyon Chir. 63(2):
266-273, 1967.

This technic has never been employed in a case
of the syndrome; the details have been worked
out in cadavers and the operation has successfully been done experimentally in the dog.
Briefly the proposed solution is the use of a
Dacron or similar prosthetic tube, connecting
the portal vein with the right atrium by the
shortest route; the mobilization of the left
lobe of the liver by section of the triangula
ligament known as Turner's maneuver in gastro-
esophageal surgery furnishes a direct pathway
from the liver, the fissure of the venous
ligament or the canal of Arantius, between th
left and the dorsal lobes of the liver; after
proper dissection the tube is implanted in th
portal vein at the atrium, passed to the thor
through the diaphragm to the left of the
falciform ligament. The upper implantation i
in the right atrium without excessive tractio
using nylon thread and double sutures. The
implantation into the right atrium is superio
to implantation in the caval vein which is mo
delicate and susceptible to stenosis. The
length of the prosthetic vessel is about 9-10

9487 EXPERIMENTAL STUDIES ON THE LYMPHAT
CIRCULATION OF THE LIVER. X. EFFE
OF LIGATING THE EFFERENT LYMPHATIC VESSELS OF
LIVER. (Fr.) Mallet-Guy, P. (Edouard Herrio
Hosp., Lyon, France), Y. Mandairon and G.
Yoshitomi. Lyon Chir. 63(2):217-225, 1967.

To trace the lymphatic channels draining the
liver, the bile duct was cannulated with the
gallbladder clamped in anesthetized dogs with
tracheal intubation and artificial respiratio
A soln. of Chicago blue (20 trials) was inj.

g a constant pressure of 50 cm H_2O; the
shold pressure was 32 cm H_2O. In a few min.
efferent lymphatics of the liver were colored;
the branches made visible were tied off by
n thread. The dogs were examined 3-8 days
r for the presence of ascites, the condition
he liver and the deposition of fibrin on the
ace. Ten trials were made by inj. of $BaSO_4$
radiography, and 3 by both technics succes-
ly. Ascites occurred in 12 cases, 50-300 ml,
latively small vol. but true ascitic fluid as
ed by fibrin deposits and by increased vol.
he liver. Biopsy revealed vascular congestion
edema of the spaces of Dissé, 6 cases showed
hatic vessels colored blue and ligated, with
race of Chicago blue in the thoracic duct,
with no visible changes; this was also true
5 cases inj. with $BaSO_4$; the remaining
als showed a true ascites but a lymphatic
on the lower face of the liver which had
ped ligation. In view of these results it
s that, in some animals at least, biliary
phatic)-blood connections must exist.

CHANGES IN BLOOD CLOTTING FACTORS AFTER MASSIVE LIVER RESECTION AND TOTAL
TECTOMY IN DOGS. (E.) Niléhn, J.-E. (U.
, Malmo, Sweden), K.-F. Aronsen and B.
sson. Acta Chir. Scand. 133(3):183-188, 1967.

(14) were subjected to liver resection
60% by wt.) and 6 to total hepatectomy; they
followed postoperatively for changes in
r blood clotting factors, fibrinogen,
inolysis and degradation products of
inogen and/or fibrin, Factors V, VIII and IX,
the prothrombin group (Factors II, VII and X).
effect of the fibrinolytic inhibitor, amino-
yl-cyclohexane-carboxylic acid, on some clot-
factors was studied in partially-hepatectomized
als. In dogs subjected to partial hepatectomy,
most marked changes were noted in prothrombin
Factor V, which 1-2 days after operation fell
0%-50%, resp., of their pre-operative values.
the prothrombin group and Factor V became
st normal within 1 wk. There was slight
rinolytic activity, and after an initial
rease, the fibrinogen level rose in a manner
logous to that after an ordinary operative
cedure. Amino-methyl-cyclohexane-carboxylic
d (0.02 g/kg given 5 times) had no substantial
ect on the various coagulation factors in
s. Total hepatectomy was followed by a
ked decrease of the prothrombin group and
rinogen. Fibrinolytic activity on heated and
eated fibrin plates was demonstrated, as well
degradation products of fibrinogen and/or
rin.

9 STUDIES ON BLOOD CLOTTING FACTORS IN MAN AFTER MASSIVE LIVER RESECTION.
) Niléhn, J. E. (U. Lund, Sweden), I. M.
sson, K. F. Aronsen and B. Ericsson. Acta
r. Scand. 133(3):189-195, 1967.

Five patients (1 woman, 4 men; 44-70 yr. old) with liver carcinoma and one 20-yr.-old male with liver rupture were subjected to massive liver resection, and the postoperative course of various blood clotting factors followed. In all 6 cases there were only minor changes in the coagulation time, bleeding time, 1-stage prothrombin time, recalcification time, prothrombin consumption and the inhibitors of activation of plasminogen by urokinase. The prothrombin group (Factors II, VII and X), Factor V, Factor IX, fibrinogen and plasminogen were all markedly decreased postoperatively. Factor V recovered preoperative levels about 1 wk. after surgery, while the prothrombin group and Factor IX reached preoperative values approx. 3-6 wk. after the operation. During the postoperative course, values of the antihemophilia factor were high in all 6 patients. The number of platelets recorded in 5 of the 6 patients tended to decrease after the operation and to reach their preoperative level 1-2 wk. after the operation. The plasminogen level was low after the operation and recovered its preoperative level 1-2 wk. after the operation. The occurrence of split products of fibrinogen and/or fibrin was also demonstrated. All coagulation factors recovered normal values 4-6 wk. after the operation.

9490 NEW POSSIBILITIES OF LIVER RESECTION AFFORDED BY CRUSHING THE PARENCHYMA UNDER A SLIDING PRESSURE (FINGER FRACTURE) WITH REFERENCE TO SIX RECENT CASES OF VARIOUS TYPES.

(Fr.) Bourgeon, R. and M. Guntz. Mem. Acad. Chir. (Paris) 93(15-16):486-496, 1967.

The usual resection of the liver follows well-regulated and anatomically-determined plans; within these limits are resections for benign tumors, inflammatory lesions and trauma; resections more limited for small malignancies, often metastatic; and large resections for malignant primary tumors. The technic of crushing the parenchyma has been used by Asiatic surgeons, demonstrated in France, and adopted by some French surgeons. The authors review 6 personal cases treated by this technic. These were (1) resection of Segment VI (Burgeon et al.) for abscess; (2) right hemihepatectomy for contusion; (3) resection of Segments IV and V for central metastases; (4) resection of Segment III for polycystic condition; (5) resection of Segment IV due to multiple metastases; (6) left hemihepatectomy due to angioma of the left lobe. These varied and extensive operations in patients 10.5-68 yr. old have been successful, with complications in 2 cases apparently caused by early removal of drains and subsequently corrected. The details of the "finger fracture" method which allows delicate realization of arteries, veins and ducts are simple and well known. The great advantage of this method is the subsequent regeneration of a healthy parenchyma. It is possible to enlarge the hilum of the liver either to the right or left; the mobilization of Segment IV is possible without uncovering the hilus. The control of blood flow is most important to prevent undue loss of blood. The stoppage of portal blood flow can be maintained for 10 min. without danger. Complete block is relieved as soon as possible by partial blood flow. Prolonged cessation of portal blood flow may cause hypertension and hemorrhage elsewhere as well as accumulation of blood in the splanchnic bed.

9491 SWELLING OF ISOLATED MITOCHONDRIAL SUSPENSIONS OBTAINED FROM NORMAL AND PATHOLOGICAL HUMAN LIVERS.

(It.) Giglio, F. (U. Palermo, Italy), L. Pagliaro, G. Migneco, S. Le Moli and A. Notarbartolo. Fegato 12(4): 455-467, 1966.

Mitochondrial swelling was studied in suspensions obtained from 8 normal subjects, 16 patients with various stages of hepatic cirrhosis, and 4 patients with acute hepatitis. Novelli's method was used, in which swelling was determined by the decrease in optical density at 520 mμ of mitochondria suspended in buffered 0.25 M sucrose at pH of 7.15, 8.2, and 5.8. Mitochondrial preparations from patients with cirrhosis showed a much slower optical density decrease at pH of 7.15 than did normal subjects, and after 20 min. the decrease was markedly less in the former group; at pH of 8.2, a marked decrease was observed in cirrhotic patients and final values in both cirrhotic patients and normal subjects were practically the same; at pH of 5.8, the decrease in cirrhotic patients was slight. In patients with hepatitis, the decrease was slightly less than in normal subjects but markedly greater than that of cirrhotic patients at pH of 7.15; the decrease was similar to that seen in normal subjects at pH of 5.8 and 8.2. The results indicate that the degree of mitochondrial swelling in patients with hepatitis is similar to that observed in normal subjects, indicating relatively moderate mitochondrial damage, at least in the acute stage of hepatitis. The relatively smaller decrease in cirrhotic patients suggests that the mitochondria are already partially swollen and their capacity for further swelling greatly reduced. These results are confirmed by previous experimental studies in which mitochondrial swelling curves at pH of 7.15, 8.2, and 5.8 of rats following incubation at 38°C were similar to those of cirrhotic patients in the present study, while the swelling curves of rats not previously incubated were similar to those of normal subjects in the present study.

9492 RELATIONSHIPS OF CHANGES IN THE TONGUE IN LIVER CIRRHOSIS AND CHRONIC HEPATITIS WITH REFERENCE TO MICROCIRCULATION AND LIVER STRUCTURE.

(Ger.) Jacoby, H. (U. Cologne, Germany) and R. Phlippen. Med. Welt 18(11):613-617, 1967.

Vital microscope examinations were made of the tongue in 106 cases of liver disorders. Examinations were made visually by means of a modified capillary microscope. Photomicrograph were also obtained. The vital visual and photo micrographic pictures presented 4 conditions: (1) the normal capillary with uniform calibers of the venular and arteriolar segments; (2) the congested capillary showing widening of the venular sector and a conic enlargement of the arteriolar segment of the capillary with an apparent cyanosis in the vascular bed especiall beyond the region of the venous plexi; (3) the "liver tongue" of Pannhorst a congested tongue with increased vol., marginal indentations of t teeth, violet-brown color, and on the underside strongly engorged veins; (4) the capillary with signs of peripheral disturbances in blood flow, showing small caliber precapillaries and following capillary segment with compensating enlargement of the venular end of the capillary; mostl accompanied by a slowed blood flow and increase cyanosis of the vascular bed, not characteristi of a single type of tongue. In the 106 cases o liver disorders (52 with liver cirrhosis, 39 with chronic hepatitis, and 15 others having chronic liver diseases such as fatty liver, cholangitis, and cholestasis), only 10 of these patients had allergies as well; because allergi states often cause the same changes in the capillary bed of the tongue these patients were not enumerated in the results. The relationship of allergy to liver diseases is quite probable, however. Some patients (16 liver cirrhoses, 9 hepatitis) showed a capillary picture of congestion (2); 47 patients (21 liver cirrhoses and 26 chronic hepatitis) presented a picture with signs of disturbed peripheral capillary circulation (4). Among the cirrhotic 8 presented a combination of capillary changes (2) and (4) as did 9 others with differing chronic liver damage. Finally, 7 patients with liver disease showed completely normal capillar beds. The appearance of the atrophic, smooth red tongue is caused by an altered metabolism o the liver, whereas the changes (2)-(4) above reflect structural changes in the blood vessels and sinusoids of the organ.

9493 CORTICOSTEROIDS IN THE TREATMENT OF CHRONIC HEPATITIS.

(Rus.) Loranskai T. I. (Inst. Nutr., Acad. Med. Sci., Moscow). Probl. Endokr. Gormonoter. 13(2):34-37, 1967.

Hormonal therapy, usually prednisolone (during the initial 1-3 days, 10-20 mg/day, then, in the subsequent 3-7 days, 30-40 mg/day, and thereafter the dose was gradually decreased; in the final 3-4 days, 10-40 U/day of ACTH, total 80-120 U, was added; the total dose of prednisolone/course was 250-500 mg in 15-20 days), was given to 33 patients (26 males, 7 females), of whom 23 had postnecrotic liver cirrhosis (17 of 23 had cirrhosis with hepatomegaly, 6 of 23 the portal form of cirrhosis) after ineffective treatment with diet and vitamins; 10 patients with chronic hepatitis (in the remission stage) with hyperbilirubinemi

also treated in this manner. In most
ents with hepatic cirrhosis, hormonal therapy
positive results: the general condition
oved, positive shifts in biochemical indices
noted (total protein level was normalized in
-globulins decreased and lipoproteins re-
ed unchanged), and a remission developed in
23 (the enzymatic activity was normalized,
dice disappeared and protein picture showed
sitive shift). When treatment was dis-
inued, there was an exacerbation in 3
ents; in the author's opinion, this was due
too rapid withdrawal of the drug. Of 3
ents who showed an increased transaminase
vity after treatment and exacerbation induced
iscontinuation of hormonal therapy, 2 died
5 days later and, in 1, remission was obtained
r repeated treatment with hormones. Treat-
was without effect in 7 patients with
tive hepatitis with hyperbilirubinemia.
-effects such as dyspeptic disorders (5),
p disorders (7) and irritability, disappeared
iscontinuation of treatment, while 2 had
sient glucosuria.

THE CONCENTRATION OF CONJUGATED SERUM BILE ACIDS IN DISEASES OF THE LIVER.

.) Frosch, B. (Med. Univ., Heidelberg, Germany).
. Deutsch. Ges. Inn. Med. 72:697-701, 1967.

w method makes possible the exact deter-
tion of conjugated bile acids in human serum
h is first extracted with hot ethanol; some
ds are separated by partition in ether,
nol, heptan and water. The final partition
ccomplished by thin-layer chromotography
h simultaneously separates serum bile acids,
bilirubins, the phosphatides, and the mono-
erides from the conjugated bile acids. This
od is capable of the quantitative deter-
tion of 0.5 μg of the individual bile acid/ml
erum. The sera of 31 normal controls showed
onjugated bile acids. In some individuals
formerly suffered from hepatitis no
ugated bile acids could be demonstrated. At
beginning of hepatitis there was a sudden
ease in the total conjugated bile acids
ng to 226 μg/ml, then falling to 15 μg/ml
in 5 wk. Both conjugates of taurocholate
glycocholate follow the same course. The
. of these compounds remained elevated after
rubin and transaminases returned to normal.
group of 23 hepatitis patients the con-
ted bile acids av. 50 μg/ml 100 days after
t of the disease, after which the return to
al was more rapid.

PARENTERAL MAGNESIUM THERAPY IN CHRONIC LIVER DISEASE.

(Ger.) Merker, G.
nrich Heine Clin. Hosp., Potsdam-Neufahrland,
any) and O. Selisko. Z. Ges. Inn. Med.
):182-185, 1967.

on, as a soln. of Mg adipinate containing
g of Mg/ml was inj. i.v., 5 ml in the first dose and 10 ml in succeeding doses, 18-20 times over 4 wk., in 24 cases of viral hepatitis, 38 of chronic hepatitis and 23 of hepatic cirrhosis. All patients received the usual therapy for liver disorders, as did other control patients who did not receive Mg inj. Fifteen patients (62.5%) of 24 with viral hepatitis who received Mg were clinically and serologically improved as compared to 5 (20.8%) of 24 without Mg. Of 38 patients with chronic hepatitis receiving Mg, 28 (73.6%) were similarly improved as compared to 13 (36.1%) of 36 without Mg. The corresponding figures for hepatic cirrhosis were 17 (74.0%) of 23 with Mg and 10 (45.5%) of 22 without Mg. The overall values were 60 (70.5%) of 85 with Mg and 28 (34.1%) of 82 without Mg. The patients received no other medication. Mg may increase blood flow through the liver tissue, as well as activate many enzymes. There seems to be a synergism between the Mg and vitamin E in reducing initial fatty infiltration of liver tissue (seen in rat experiments) which needs confirmation in man.

9496 IRON DISTRIBUTION IN THE LIVER OF PATIENTS WITH THALASSAEMIA MAJOR.

(E.) Berry, C. L. (Hosp. Sick Child., London) and W. C. Marshall. Lancet 1(7498):1031-1033, 1967.

Liver distribution of Fe was studied in 17 patients with thalassemia major; 7 (5 males, 2 females; 3.9-12 yr. old) were not splenectomized and 10 (4 males, 6 females; 4-13.5 yr. old) were splenectomized. The mean and range of serum Fe in splenectomized and nonsplenectomized groups was 189.7 (148-240) μg/100 ml and 183.4 (156-196) μg/100 ml, resp. Serum Fe-binding-capacity was comparable in the 2 groups, the mean (and range) being 257.2 (193-399) μg/100 ml in splenectomized individuals and 261.1 (197-342) μg/100 ml in nonsplenectomized patients. Liver biopsy (with a modified Vim-Silverman needle) revealed hepatic structure that was generally well maintained but had frequent portal fibrosis. No significant fatty change was observed in any case. Two main types of Fe storage were found: 1) parenchymal, with widespread heavy deposition of stainable Fe in parenchymal cells, associated Fe-distended macrophages in portal areas and Fe-containing Kupffer cells; and 2) nonparenchymal, with heavy loading of Kupffer cells, the presence of many Fe-distended macrophages and some free Fe in portal areas but with little involvement of parenchymal cells. The latter type of storage was found in splenectomized patients; the parenchymal type was found in splenectomized patients. The site of storage was not correlated with age, sex, diet or severity of the disease (as judged by transfusion requirements). It did not seem likely that the spleen, by its capacity to store Fe, prevented hepatic Fe storage exceeding a certain level. These findings would seem to indicate a further contraindication to removal of the spleen.

9497 CURRENT SURGICAL TREATMENT OF HYDATID CYST OF THE LIVER AND ITS PRINCIPAL COMPLICATIONS: 600 OPERATED CASES. (Fr.) Guedj, P. (U. Constantine, Algeria), J. Gairoard, F. Morvan and J. Bogaert. J. Chir. (Paris) 93(2): 191-216, 1967.

Simple drainage, alone or preceded by partial cystectomy of external cysts, was the treatment of choice, even when the disease was severe; healing was rapid (av. 10-20 days) and the mortality was low (2% in the last 100 cases). Total cystectomy was indicated primarily in the presence of calcified hydatid cysts (3% of the group) and was sometimes associated with biliary tract surgery. The cysts opened into the biliary tract in 2.3% and compressed it in 1.65% of the group; acute hydatid cholecystitis was treated by cystectomy with cholecystectomy (simultaneously if possible); drainage procedures were less effective. Biliary lithiasis associated with hydatid cysts was noted in 7% of the group. Lung and bronchial involvement (2.8% of the group) was treated by drugs (e.g., pyramidone) or blood transfusions before surgery was attempted. Partial hepatectomy was rarely performed, and indicated only in patients with massive involvement of 1 liver lobe or active exogenous foci deeply infiltrating the liver parenchyma around a cyst. In the entire group of 600 patients, the mortality rate was 5.6%.

9498 EXPERIMENTAL HEPATIC COMA: EFFECT OF EXCHANGE TRANSFUSION ON METABOLISM AND SURVIVAL. (E.) Turcotte, J. G. (U. Michigan Med. Ctr., Ann Arbor), W. J. Mattson, Jr. and C. G. Child III. Surgery 62(1):189-194, 1967.

Hepatic coma was induced in 17 pairs of beagle dogs by fashioning an end-to-side portacaval shunt, and 24 hr. later ligating the common hepatic artery. In 1 member of each pair, a vol. of blood equal to 7% of body wt. was exchanged, and in the second member of the pair, a sham-exchange (blood withdrawn was reinj.) was done. The duration of survival after hepatic artery ligation was prolonged an av. of 16 hr., when dogs with equivalent liver damage were compared; no significant prolongation in survival was observed when the entire group of control and experimental animals were compared. Initial signs of hepatic coma were noted 4-18 hr. after hepatic artery ligation. During 70% of exchange transfusions performed while dogs were in coma, evidence of revival from coma was noted. Immediately after each exchange there was a significant decrease in SGOT and alkaline phosphatase, and a significant increase in lactate and pyruvate. Blood urea nitrogen and creatinine tended to rise, K and glucose decreased, and Na, P and Cl did not appreciably change. There were slight increases in phosphate and WBC, and hematocrit changed little. The changes in blood chemistry after exchange transfusion were the result of dilution, the addition of constituents in the donor blood and the continued effects of hepatic failure during the 1 hr. required for e change. Arousal from coma seen in animals duri exchange transfusion, and prolongation of life noted when animals with equivalent hepatic inju were compared, support the concept that exchang transfusion may be beneficial in some cases of hepatic come. When severe hepatic injury was present, exchange transfusion of 1 blood vol. h no demonstrable benefit in this experimental model.

9499 DISTURBANCES OF METABOLISM OF SINGLE AMINO ACIDS IN HEPATITIS AND HEPATIC CIRRHOSIS. (Ger.) Gerok, W. (U. Mainz, German and P. Bornhäuser. Verh. Deutsch. Ges. Inn. Me 72:692-697, 1967.

An investigation of the metabolism of histidine and methionine in cases of hepatitis and hepati cirrhosis was undertaken. The amino acids were determined by a quantitative columnar chromatographic technic. Formiminoglutamic acid was measured enzymatically through the use of formi glutamic transferase and cyclodeaminase obtaine from hog liver. Urocanic acid and additional imidazole derivatives were determined quantitatively by thin-layer chromatography. No significant difference was found in the normal controls with respect to urinary histidine excretion before and 24 hr. after oral loading, 226 and 243 mg/day, resp.; but among those with acute hepatitis the av. urinary excretion was 323 and 446 mg/day, and for those with hepatic cirrhosis 347 and 474 mg/day, resp. Urinary excretion (for 8 hr.) of formiminoglutamic acid in the controls without oral dosage of histidin was 1.1 μMol and with oral dosage 23.5 μMol; th corresponding fiqures in acute hepatitis were 8 and 146; in cirrhosis 5.2 and 137.5, resp. Liv disease patients also excreted imidazolactate a urocanic acid which could not be demonstrated in the urine of the controls. This indicates that the breakdown of histidine in hepatitis and in hepatic cirrhosis is inhibited by the transfer of 1 atom of carbon to tetrahydrofolic acid, resulting in the significant increase in formiminoglutamic acid. In liver disease a compensatory increase in deamination or in transamination into imidazolactactate occurs. One of the largest reactions in normal metaboli of methionine is the hydrolysis of a methyl group from activated methionine with the formation of homocysteine which, through the cystathionines, is split into cysteine and homoserine. This is the main route in the breakdown of methionine; a secondary pathway with only a very small rate is through α-keto-methiolbutyric acid and α-keto-butyric acid to α-aminobutyric acid. If the normal serum conc. of methionine, α-aminobutyric acid, cysteine, and serine are each taken as 100%, then the av. of these compounds in 10 patients with cirrhosi were 270, 225, 104 and 120%, resp. In hepatic cirrhosis the secondary pathway becomes

portant in the metabolism of methionine. It
suggested that these metabolic pathways and
oduct conc. may be of diagnostic value in
ver disease.

00 THE ELECTROLYTES OF PERSPIRATION DURING CHRONIC LIVER DISEASE IN THE ADULT.
r.) Bourel, M. (U. Rennes, France), P. Lenoir,
Pawlotsky, D. Pirot, P. Miel and A. Chauvel.
est Med. 20(9):642-648, 1967.

e salt conc. of perspiration was measured in
subjects with alcoholic hepatic cirrhosis,
iopathic hemochromatosis, diabetes mellitus,
ronic bronchopneumonia, and a control group.
e perspiration was collected in ashfree filter
per suitably protected by a sheet of poly-
hylene, applied to a carefully-prepared
esternal area inj. cutaneously with 0.2-0.4
of physostigmine in four places 4 cm apart.
e data showed that the electrolytes excreted
the perspiration were normal in the 16
rrhotic, somewhat elevated among those with
iopathic hemochromatosis (16), and decidedly
ised in the diabetics. The vol. of perspiration
peared high among those with hemochromatosis
d bronchopneumonia.

01 SUBTOTAL HEPATECTOMY FOR PRIMARY HEPATIC CARCINOMA. (E.) Moloney,
E. (Radcliff Infirm., Oxford, England).

6 ROLE OF THE NERVOUS SYSTEM IN THE
DEVELOPMENT OF EXPERIMENTAL HEPATITIS.
s.) Chernin, V. V. (Saratov Med. Inst., USSR).
n. Pat. 29(3):50-53, 1967.

150 rabbits (both sexes; 330-4000 g wt.), the
ebral cortex was removed in 109, vagus nerve
ers were resected in 10, a partial mechanical
turbance of the solar plexus was induced in 9,
effect of ether narcosis on the condition of
liver was studied in 7, and 15 served as
trols having no surgery. No effect was noted
n ether narcosis. Intact animals showed no
ar borders between hepatic lobes, and hepatic
ls were arranged in deep ridges or depressions.
ediately after surgery (within the first few
s) the liver showed pronounced vascular dis-
ers which were manifest macroscopically in
egular polyemia of the organ; individual
tions showed dilated and blood-filled central
ns, and arteries, interlobular veins and inter-
ular capillaries; the hepatic lobes were
nged slightly. In the subsequent 3-7 days
re was extensive focal hyperemia, serous
lammation, hemorrhages, and dystrophic destruc-
e and necrotic changes of the hepatic parenchy-
After 7-12 days, inflammatory infiltration
eared at the sites of hemorrhages, and degenera-
e and necrotic changes; the rabbits developed
rrhea. Toward the third-fourth wk., hepatic
eremia markedly decreased and stasis dis-
eared; connective tissue appeared in the
enchyma and interlobar spaces. At 34 days
er surgery, inflammation disappeared and
nective tissue growth was distinct (it resembled
al cirrhosis); the animals were in good con-
ion, gained wt. and had no dyspeptic disorders.
a later period of observation (after 3-8 mo.),
condition of these rabbits exacerbated, usual-
in the spring and fall; at sacrifice, there
hepatic hyperemia, edema and stasis, i.e.,
process in the liver assumed a recurrent
rse and each exacerbation induced more pro-
nced morphologic changes. It is suggested that
the pathogenesis of acute and chronic hepatitis,
ions in various parts of the nervous system
play a definite role.

7 BIOCHEMICAL CHANGES IN RAT LIVER AFTER
ACUTE BERYLLIUM POISONING. (E.)
schi, H. P. (Med. Res. Council Lab., Carshalton,
rey, England) and W. N. Aldridge. *Biochem.*
rmacol. 16(2):263-278, 1967.

er male, Porton albino rats weighing 180-200
eceived beryllium (0.75 mg/kg, i.v.; LD$_{50}$ =
4 mg/kg, i.v.), the rate of disappearance of
er glycogen was comparable to that of controls
ing the first 8 hr. of fasting; after 30 hr.
fasting, however, liver glycogen conc. was 10
es as great as that found in controls. When
^{14}C]-labeled glucose was inj. i.v. at intervals
less than 6 hr. after poisoning, the amount of
eled glucose found in liver glycogen, 50 min.
later, was the same as that found in controls. When a comparable inj. was made 6 hr. after intoxication, the amount which appeared in liver glycogen was approx. 60% greater than that found in controls and the difference continued to increase progressively with the interval between poisoning and glucose admin. up to 24 hr. There were no significant, concurrent changes in terms of blood sugar level or specific activity of serum glucose. It was impossible to demonstrate the presence of glucose-1-phosphate in the livers of normal controls or in those derived from treated rats 2, 5 and 24 hr. after poisoning, although previous studies had shown that beryllium was a powerful inhibitor of phosphoglucomutase *in vitro*. The microsomal, lysosomal and mitochondrial enzyme systems did not appear to be affected significantly by the presence of the metal. It is concluded that the specific mechanisms of action through which beryllium induces necrosis of the liver could not be defined, and that a satisfactory biochemical explanation for its necrogenic activity remains to be found. Particular attention is drawn to the fact that the metal induced severe necrosis without significant early inhibition of protein synthesis.

9568 COMPARATIVE STUDY OF THE LIVER OF RATS TREATED WITH CHOLIC AND LITHOCHOLIC ACID, ALONG OR ASSOCIATED WITH BUTTER-YELLOW. (Fr.) Lacassagne, A. (Radium Inst., Paris), N. P. Buu-Hoi and L. Hurst. *Tumori* 53(1):43-54, 1967.

Male rats (380 g) were maintained on a semisynthetic diet poor in protein and riboflavin. To each kg of this semisynthetic diet was added 0.6 g of paradimethylaminobenzene (butter yellow) and 0.5 g of cholic acid fed to a second group. The same amount of lithocholic acid was substituted for cholic acid in the food of a third group. Animals were sacrificed between 126-278 days. A second set of experiments were carried out on male rats of the same av. wt. on a normal diet. To 1 kg of food 0.5 g of cholic acid was added for 1 group and 0.5 g of lithocholic acid was added for another group. No butter yellow was added to the diet of these animals. In the first set of experiments both cholic and lithocholic acids showed no accelerating action on the carcinogenicity of butter yellow. In fact, the daily admin. of lithocholic acid delayed the appearance and the succession of the stages produced by the toxic action of butter yellow admin. alone; cholic acid produced a similar effect with less retardation. Rats of the second set of experiments receiving cholic acid were sacrificed between 32-362 days. Rats receiving lithocholic acid only in this set of tests were sacrificed after 28-372 days The livers had increased by about 2 g in these animals but did not show any consistent pathologic change. There was not much difference between those receiving cholic acid and those receiving lithocholic acid. The general body wt. decreased in the first mo. but then increased somewhat (up to 100 g) for those on cholic acid. This addition tended to diminish and disappear in the animals on lithocholic acid. General toxicity was somewhat less with lithocholic than with cholic acid. This paradoxical effect of cholic and lithocholic acid upon carcinogenesis may, in part, result from the strain of rat used; all animals in these experiments were Wistar rats.

9569 HISTOLOGIC AND ULTRASTRUCTURAL STUDY OF EXPERIMENTAL HEPATIC FIBROSIS IN THE RAT AND THE PROTECTING EFFECT OF "HYMECHROMONE." (Fr.) Garrone, R. (Fac. Sci., Lyon, France), M. Pavans De Ceccatty, J. Chabert and L. Fontaine. C. R. Acad. Sci. (Paris) 264(11)(Ser. D):15[illegible]-1552, 1967.

Consecutive pathologic alterations were produced in the livers of white rats by biweekly inj. of CCl_4 (0.05 ml/100 g body wt.) for more than 2 mo. Liver tissue obtained at intervals during the time of CCl_4 admin. was examined by optical and electron microscopy with special attention to alterations and necrotic processes in the hepatocytes during advancing sclerosis. The objectives of this research were (1) the determination of critical stages during the degenerative changes, and (2) the testing of the compound, hymechromenone (H) (hydroxy-7,methyl-4,oxo-2, chromene-3), 400 mg/kg admin. in the daily ration; this substance has been reported to retard the toxic effects of CCl_4 when admin. simultaneously. The results were: (1) The hepatocytes at the onset of intoxication showed massing of smooth membranes marking a hyaline degeneration, then the cisternae of the reticulum formed vacuoles bringing about the characteristic appearance of a fatty, ballooning cell. Much later, in the mitochondria spherical opaque masses with a diameter of 1000-6000 Å were formed; these are reported to be $Ca_3(PO_4)_2$; the massive entrance of calcium, an inhibitor of oxidative phosphorylation, blocks the synthesis of ATP. This is the point of no-return. (2) The ballooning of the parenchyma proceeded (at the dosage of CCl_4 employed) rapidly for 15 days, then advanced more slowly until about 1 mo. when the number of ballooning cells became stabilized at 60% of the parenchymal area. As the area of the lost tissue reached 60%, the proliferation of collagen proceeded in 3 definite stages: In the 1st stage, fibrogenesis was perivascular and perisinusoidal; in the 2nd, periductal; and in the 3rd, intraparenchymatous which was the most intense stage and a landmark in the histologic restoration of the liver. The process of fiber formation is described. The series of tests with H showed that this substance to a degree did have an effect in protecting liver cells against CCl_4 within the time limit of the experiment.

9570 AUTOANTIGENICITY PHENOMENA IN CHRONIC EXPERIMENTAL HELIOTROPIN TOXICITY OF THE LIVER (TRANSMISSION OF THE AUTOIMMUNE COND TION). (Rus.) Burshtein, C. I. (Tashkent Med Inst., USSR). Vestn. Akad. Med. Nauk SSSR 22(2):34-35, 1967.

Normal Wistar rats received i.v. serum from ra with heliotropin (piperonal) toxic hepatitis (1.5-2.0 ml for 5-6 times, with a 2-3 day inte between inj.; the last inj. was through the portal vein); when sacrificed 1.5 mo. after th last inj. of serum, the rats had hepatitis wit pronounced dystrophy of the hepatic cells, deranged blood circulation, microcellular infilt tion, Küppfer cell hyperplasia, serum protein changes, increased activity of serum transamin and autoantibodies to their own liver extract. Controls (inj. with serum from healthy animals had similar, but less pronounced, histological changes without blood circulation changes; the blood displayed globulinemia (β-γ-globulins), hypoalbuminemia and a slight increase in serum transaminase activity. Lymphoid elements from mesenteric nodes (7-14 x 10^6 cells, admin. i.v at the time of donor sacrifice, and 10-20 x 10 cells admin. i.p. on the next day) of 95 donor with hepatitis were transferred to 31 recipien this established the following controls: 1) 1 nodes of healthy rats; 2) tissue from skeletal muscle of sick donors; 3) serum of rats with piperonal toxic hepatitis; and 4) piperonal (1 mg). Recipients showed definite changes in liver function, including a distinct increase the absorption of Rose Bengal by the liver as early as 1-2 wk. after inoculation. After 1-2 mo. the amount of absorption was decreased, an in several cases it remained above initial val No consistent changes were found in the contro group. Experimental animals, sacrificed 2.5-3 mo. afterward, had acute hepatitis with activa tion of the reticulo-endothelial system, nucle hyperchromatosis, hepatocytic hypertrophy and pronounced nuclear polymorphism; they also had edema of the mesenteric node capsule, sinus enlargement, reticular tissue hyperplasia and follicular atrophy. Also found were autoantibodies against liver tissue, decreased serum albumin and increased serum globulin, as well a positive thymol turbidity test. Controls ha either an absence or a low titer of autoantibodies, unchanged lymph nodes and a mild form hepatitis. Studies are still in progress, but in rats treated with serum from "piperonal" ra the absorptive powers of the liver were somewh decreased. In rats treated with piperonal and skeletal musculature there were no changes fro the normal.

9571 ESTERASES AND CLEARING FACTOR LIPASE IN EXPERIMENTAL RAT LIVER INJURY. (Katz, S. (P. B. Churruca Hosp., Buenos Aires, Argentina) and B. Kaplún. Acta Physiol. Lat. Amer. 16(3):241-248, 1966.

Esterolytic activity in liver and plasma was studied in rats after the i.p. inj. of CCl_4 or surgical ligation and excision of the common b

t using α-naphthyl esters, coconut oil and
en 60 as substrates. The principal changes in
erase activity were noted in the liver in cases
n obstructive jaundice, and in liver and plasma
er admin. of CCl_4. In both types of experi-
ts, there was a considerable decrease in the
sma-clearing-factor lipase.

2 EFFECTS OF VARIOUS ANAESTHETICS ON THE
METABOLISM AND GENERAL CONDITION OF THE
LATED PERFUSED RAT LIVER. (E.) Bloxam, D. L.
iv. Coll., London). Biochem. Pharmacol. 16(2):
-294, 1967.

ious anesthetics were added to the perfusion
ium of an isolated perfused rat liver prepara-
n and their effect on glucose and urea produc-
n was measured; the general condition of the
er was also assessed using the criteria of
er K levels, water content and bile secretion.
tobarbitone sodium, thiopentone sodium and
bromoethanol all caused a marked inhibition
glucose output, urea production and bile secre-
n from the liver. Halothane had relatively
tle effect on glucose and urea production at
erfusate conc. 15-20 times that present in the
od of rats under deep halothane anesthesia,
the effect was immediately reversed after
in. of the vapor was stopped. The criteria
oted also showed that it caused little or no
uctural damage to the liver at the same conc.
chloroethylene, at a perfusate conc. of approx.
imes that to be expected in the blood of an
sthetized rat, inhibited glucose and urea
out, and the loss of intracellular K and gain
water indicated that it caused extensive damage
the liver; therefore it is likely to be poten-
lly damaging in man. The liver K levels of
s kept under trichloroethylene anesthesia for
min. were slightly lower than those of rats
er halothane anesthesia for the same length
time. The production of liver necrosis by
ogenated hydrocarbons is discussed in the
ht of these findings.

3 ENZYMATIC BEHAVIOR IN EXPERIMENTAL
NOVOBIOCIN-INDUCED JAUNDICE. (It.)
ci, G. P. (U. Rome), G. Cucchi, A. De Arcangelis,
Rendace and A. Alessandrini. Epatologia 12(5):
-848, 1966.

er glucuronyl-transferase activity was studied
Sprague-Dawley rats treated immediately after
th with novobiocin (250 mg/kg/day in physio-
ical saline s.c.). Animals were kept under
ervation for 12-24 hr. and sacrificed several
after the appearance of jaundice. After re-
ing the livers, glucuronyl transferase activity
determined according to the Brown and Henning
hod, using orthoaminophenol or beta-methyl-
elliferon as glucuronide acceptors. Spectro-
tometric readings (wave length = 336 Å) were
formed immediately after the addition of
otinamide-adenine-dinucleotide (NAD). After
hr., novobiocin-treated rats showed wt. loss,
reduced liver vol., and jaundice especially in the proximal region of the tail as compared to untreated controls. With ortheaminophenol, glucuronide transferase activity was markedly lower in novobiocin-treated animals than in controls; with beta-methylumbelliferon, glucuronide transferase values were lower in treated rats than in controls, but not significantly so. Liver glycogen studies (Kemp method) gave variable results, but levels were generally lower than those observed in controls, an indication that liver glycogen reserves are also depleted. Results indicate that novobiocin inhibits liver glucuronyl transferase activity, necessary for the conjugation of bilirubin with glucuronic acid in the process of hepatic bilirubin formation. Since this inhibition occurs also in the liver of newborn animals in which the enzyme system is not completely developed, the authors recommend further studies with novobiocin to clarify some of the alterations found in congenital nonhemolytic jaundice.

9574 SERIAL MASSIVE HEPATIC RESECTIONS IN CIRRHOTIC RATS. CHANGES IN IN VITRO GROWTH OF LIVER CELLS. (E.) Hays, D. M. (Child. Hosp., Los Angeles, Calif.) and S. Okumura. J. Surg. Res. 7(6):270-275, 1967.

Fifty rats were inj. s.c. biweekly (for 11 wk.) for a total of 3 ml CCl_4 with weekly inj. vol. increasing with wt. (initial wt. 125 g; final wt. of 19 survivors, 365 g). Nine rats were sacrificed for sterile liver specimens at three 21-day intervals after completed regimen. Ten were subjected to 5 serial subtotal hepatic resections, beginning at the end of inj. and continuing at 3-wk. intervals for 12 wk. Another 120 rats were maintained on a standard diet until the age of 5 wk. and were than placed on a choline-deficient diet for 5 mo., during which time they received CCl_4 inj. (total 2.7 ml/rat) twice weekly for 17 wk., beginning 1 wk. after initiation of the new diet. Of these, 85 survived (av. wt. 325-375 g). From these, 70 controls (Group 1) were sacrificed and liver cells cultivated at 3-wk. intervals during and after the regimen. Others in this group were selected at random for 3 resection schedules (to assess in vitro cultivatability at different phases in the hepatotoxic process), each including 5 serial subtotal hepatic resections carried out at 21-day intervals. Group 2a included 10 in which resections began 2 wk. after initiation of hepatotoxic admin.; Group 2 b included 10 in which resection began at 16 wk.; Group 2c included 10 in which resections began 4 wk. after completion of the hepatotoxic regimen. A sixth resection was performed in Groups 2a and 2c 7 wk. after completion of regimen (after prolonged return to the normal diet). Livers from rats made cirrhotic by either regimen yielded cells with greater in vitro cultivatability than normal liver cells of rats of the same age. Rats with experimental cirrhosis, subjected to serial subtotal hepatic resection, yielded a further increase in cell proliferation when liver resections were begun during the actual hepatotoxic process. This increase was less marked that the accelerated in vitro proliferation occurring with cells from normal noncirrhotic rats after serial subtotal resection. Tissue from cirrhotic rats, subjected to resection after conclusion of hepatotoxic regimen, showed little increase in cultivatability.

9575 POSTOPERATIVE MASSIVE LIVER NECROSIS. A CLINICAL AND PATHOLOGICAL STUDY. (E.)

Babior, B. M. (Boston City Hosp., Mass.) and C. S. Davidson. New Eng. J. Med. 276(12):645-652, 1967.

The National Halothane Study made available for investigation 71 postoperative cases of autopsied massive liver necrosis. By clinical analysis these patients were classified into 2 groups, representing different types of liver necrosis. Independent "blind" analysis of liver histology yielded similar results. Agreement between the 2 modes of classification was almost complete. Fifty-six cases were classified as necrosis that followed vascular insufficiency due to severe shock, heart failure or both. Of these patients only 20% had jaundice. Cardiovascular insufficiency always preceded the jaundice. Although the lesions were extensive and severe, outlines of liver cells and cords were better preserved than in necrosis induced by drugs or virus. Of the 15 patients whose necrosis was not explained by vascular failure, 3 had hepatitis (assumed to be viral) before surgery, leaving 12 with no obvious cause for the liver disease. These 15 progressed rapidly from relatively good health through fever, jaundice and coma, to death ensuing within a wk. of the first symptoms. All but 2 (about 90%) were jaundiced. Hypotension appeared only terminally. The necrosis was indistinguishable morphologically from viral hepatitis, but because nearly all received halothane, it is suggested (but not proved) that this drug may also cause the lesion. Halothane was admin. to only 29.7% of the 800,000 patients in the National Study, and of the 59 whose liver necrosis could be explained by vascular insufficiency or preexisting hepatitis about the same figure, 33% received halothane. If halothane does cause massive liver necrosis, it does so rarely. Thus, histologic postoperative liver necrosis is most commonly associated with vascular insult, with few of the clinical findings of the better known but much less frequent acute yellow atrophy of assumed drug or viral etiology.

9576 EFFECT OF IN VIVO AND IN VITRO ETHANOL ADMINISTRATION ON LIVER LIPID PEROXIDATION. (E.)

Comporti, M. (U. Tennessee Med. Units, Memphis), A. Hartman and N. R. Di Luzio. Lab. Invest. 16(4):616-624, 1967.

Female Sprague-Dawley rats were fasted for 13 hr. before receiving, by p.o. intubation, either a single dose of 50% ethanol in the amount of
6 g/kg, or isocaloric glucose; the antioxidant
N,N'-diphenyl-p-phenylenediamine was admin. i.
as a corn oil suspension and given in the amou
of 60 mg/100 g at intervals of 48, 24 and 2 hr
before glucose or ethanol admin., while contro
received only corn oil i.p. The effect of in
or in vivo admin. of ethanol on liver peroxida
was estimated by the amount of malonaldehyde
formed by incubated liver homogenates. Ethano
increased lipid peroxidation 1-12 hr. after p.
intubation, but no difference was seen at 24 h
Enhancement of liver lipid peroxidation occurr
before increase in liver triglyceride conc., w
was seen at 2 hr. Ethanol-induced enhancement
liver triglyceride conc. was manifested throug
the 24-hr. experimental period. An increase
peroxidation of rat liver homogenates occurre
after addition of ethanol in vitro. When the
antioxidant N,N'-diphenyl-p-phenylenediamine w
admin. either in vivo or in vitro, lipid perox
tion was inhibited to a comparable degree in
presence or absence of ethanol. Liver trigly
accumulation in N,N'-diphenyl-p-phenylenediam
ethanol treated animals was markedly reduced,
when compared to the ethanol-treated group.
results support the previously proposed hypoth
of lipoperoxidation as a possible fundamental
mechanism of the acute ethanol-induced fatty
liver.

9577 TETRACYCLINE-INDUCED FATTY LIVER IN NONPREGNANT PATIENTS. A REPORT OF

CASES. (E.) Perers, R. L. (U. Southern Cali
Los Angeles), H. A. Edmondson, W. P. Mikkelse
and D. Tatter. Amer. J. Surg. 113(5):622-632
1967.

Autopsy material was examined from 6 nonpregn
women who had died unexpectedly after hospita
tion for a variety of medical and surgical co
tions. All 6 had received a substantial amou
of tetracycline i.v. (9-27 g). The liver of
these patients had undergone the foamy type o
fatty degeneration peculiar to tetracycline
toxicity. The most severe degeneration was i
the central 33-75% of each lobule and was see
as a fine, foamy vacuolization accompanied by
partial dissolution of intercellular membrane
Residual necrotic cells were rare but pigment
and cellular debris in Kupffer cells gave evi
of cellular death. All 6 patients had a hist
of nausea, vomiting and altered consciousness
some patients were feverish as well. These
conditions were usually seen after partial
recovery from the diseases which had required
hospitalization. The condition of 3 patients
deteriorated after tetracycline therapy. The
other 3 patients were already seriously ill w
such therapy was initiated. In the literatur
the deaths of nonpregnant patients with fatty
liver associated with tetracycline admin. can
be attributed to the antibiotic directly as a
patients were seriously ill at the time of
admin. In the present study, hepatic changes
were the major pathologic findings in 4 of th
patients and were accepted as the cause of de

hough clinical and laboratory evidence of
right hepatic failure was not significant.
um transaminase activity and bilirubin levels
3 of these patients were slightly elevated.
sma prothrombin activity was markedly depressed.
is concluded that in these 4 patients death
due to the effects of tetracycline.

78 THE EFFECT OF AGE, SEX AND VARIOUS
HORMONAL TREATMENTS ON THE LEVELS OF
LIVER PROCAINE ESTERASE IN VITRO. (Fr.)
deur, J. (U. Montreal, Canada), J. Y. Côte,
Nantel and P. Auger. Rev. Canad. Biol. 26(2):
-140, 1967.

e and female white rats (6-90 days old) were
led by decapitation, tissues rapidly excised,
ghed and homogenized in an appropriate vol. of
arbonate Krebs-Ringer soln. (pH 7.4). Hormones
e inj. s.c. (2 mg/kg body wt./day) for 21 days
corn oil. The activity of procaine esterase
measured in terms of 1 of the products, para-
nobenzoic acid determined colorimetrically.
U was 1 µg of paraaminobenzoic acid formed
10 mg of tissue in a period of 20 min. under
ndardized conditions from 0.3 ml of 3 x 10^{-3}
rocaine. The procaine esterase activity of
ney, lung, and testis was approx. 10% of that
the adult male liver (6.3 U). Brain, heart,
cle, skeleton and adrenal glands were incapable
hydrolyzing procaine. The liver activity was
sured in the normal rats from 6-90 days of age.
h male and female rats were inj. s.c. with
n oil only, testosterone, estradiol, progester-
, norethandrolone, cortisone, hydrocortisone,
deoxycorticosterone. Some male rats were
trated at 24 days and others at 60 days. Some
ales were ovariectomized. The LD_{50} of procaine
275 mg/kg in immature animals and 280 in adult
s (route not stated). Between 6 and 12 days
age procaine esterase activity was 0.6 U in
e livers and 1.0 U in the female; from days
2 the activity increased more rapidly in the
e than in the female in approx. rectilinear
ner, reaching 6.3 and 3.6 U, resp.; the activi-
s were apparently uniform between 60 and 90
s. Ovariectomy (5.3 U) and admin. of testoster-
(7.5 U in the male, 5.2 U in the female)
reased activity as did norethandrolone in the
ale (6.2) but not in the male. Castration at
days reduced procaine esterase activity to
and at 60 days to 5.1 U. Treatment of the
e with estradiol (3.3 U) or progesterone
6 U) reduced activity.

AUTONOMIC NERVOUS LESIONS IN VIRAL HEPATITIS AND LIVER CIRRHOSIS. (E.)

lesco, S. (Inst. Med., Bucarest, Rumania).
Neuroveg. (Wien) 29(3):385-425, 1967.

natomical and clinical study of the right
ac ganglion in fatal viral hepatitis and
tic cirrhosis was made in 12 patients by com-
son of the clinical data and histopathology
he liver and the histopathology of the celiac
lion. The autonomic nerve lesions were studied
cially by means of Troitsky's silver block
egnation, and also by Bielschowsky's impreg-
on, Nissl's method, and other staining technics.
various autonomic lesions observed could be
idered to parallel the hepatic lesions and
r dynamics. The findings were minimal recent
nomic nerve cell lesions in viral hepatitis
child; reduced nervous lesions of the dys-
nic and irritative type in viral hepatitis in
ts with prevalent necrosis of the hepatic
s; intense autonomic nervous lesions in viral
titis associated with anterior gastritis pro-
es; various associated autonomic lesions of
acute and chronic type in recent necrotic
titis associated with older precirrhotic
ons; nervous lesions, especially of the
nic type with intense, ball phenomenon and
nological changes of the synapses in liver
nosis. The autonomic nervous lesions observed
nonspecific and their significance results
from the comparison with the dynamics of the
tic lesions, the clinical data, and the history.

PROBABLE POSTTRANSFUSION HEPATITIS DURING THE COURSE OF CIRRHOSIS. (E.)

ar, J. (Chicago Med. Sch., Ill.), B. Chomet,
. Korn and H. J. Zimmerman. Arch. Intern.
(Chicago) 120(2):193-201, 1967.

pisode of acute jaundice that was assumed to
esent posttransfusion hepatitis was observed
ach of 7 patients (all alcoholics; 5 males,
males; 33-64 yr. old) with an established
nosis of cirrhosis, 30-190 days after re-
ing 1 or more blood transfusions. In 1 pa-
t, no new subjective complaints were recorded;
he other 6, variable degrees of malaise, anor-
, nausea and epigastric fullness appeared
tively abruptly at the time of the acute epi-
. Jaundice was intense in 3 patients, with
rubin levels that ranged from 19-29 mg/100 ml;
patients it was moderate (7.7 and 11 mg/100
and in 2 it was slight (4.7 and 5.0 mg/100 ml).
patients died during the acute episode of
umptive hepatitis; of the 5 who recovered
the acute episode of jaundice, 2 died 7 and
o. later, apparently from cirrhosis. In
7 patients there was a marked rise of SGOT
es between 500-1000 U during the episode of
dice; in 5 patients who had both SGOT and SGPT
rminations, the SGPT value, although elevated,
less increased than SGOT. The thymol turbidity
es rose appreciably in 5 of 7 patients, from
previously normal or slightly elevated values, to more markedly abnormal levels. In 4 patients, the alkaline phosphatase value was higher during the episode of presumed hepatitis than it had been on previous occasions. Histologic abnormalities during the bout of jaundice consisted of the obvious cirrhosis with varying degrees of acute parenchymal degenerative change, inflammation and focal areas of necrosis; free hyaline bodies were seen in only 2 patients; 1 of them also had more extensive hepatic necrosis than the other patients who were studied during the episode of presumptive hepatitis. Another patient who died during the acute episode of presumptive hepatitis had no more extensive necrosis than that of the patients who survived. In general, parenchymal abnormalities and inflammation observed during or after the episode of jaundice were qualitatively similar to those observed in the earlier biopsies, although somewhat more severe. On the basis of these cases, it is suggested that viral hepatitis of the serum variety may occur in patients with established cirrhosis, and that these instances can be recognized from biochemical data and suspected from the clinical data.

9598 BILIRUBIN AND GLUCURONIC ACID CONTENT IN SPINAL FLUID OF PATIENTS WITH VIRAL HEPATITIS. (It.)

Maddaluno, R. (U. Rome). Epatologia 12(5):849-863, 1966.

Bilirubin and glucuronic acid levels were determined in the serum and spinal fluid of 20 male patients (age 14-63 yr.) with viral hepatitis and 8 normal male subjects (age 8-48 yr.). Bilirubin levels were determined by spectrophotometry and ranged from 12-40 mg% (av. 22.9 mg%) in the serum of hepatitis patients as compared to 0.1-1.15 mg% (av. 0.47 mg%) in the serum of normal subjects; in hepatitis patients, direct serum bilirubin levels ranged from 6-30 mg% (av. 10.5 mg%) and indirect serum bilirubin ranged from 2-15 mg% (av. 7.4 mg%); in normal subjects, indirect bilirubin levels were slightly higher than direct bilirubin levels in all cases. Bilirubin was not present in the spinal fluid of normal subjects. Total bilirubin content in the spinal fluid of hepatitis patients ranged from 0.15-0.97 mg% (av. 0.41 mg%); direct bilirubin content ranged from 0.1-0.7 mg% (av. 0.29 mg%); indirect bilirubin was present in only 13 of 20 patients, av. content 0.17 mg%. In normal subjects, av. glucuronic acid content (Fishman method) of the serum and spinal fluid was 2.57 mg% and 2.28 mg%, resp. Glucuronic acid content was much higher in the serum and spinal fluid of hepatitis patients, av. levels being 5.5 mg% and 4.93 mg%, resp. Results indicate high serum bilirubin levels in persons with high serum glucuronic acid levels. Patients with high spinal fluid levels of glucuronic acid also showed high spinal fluid levels of bilirubin. The authors concluded that the presence of bilirubin in the spinal fluid is due to direct passage across the blood-spinal fluid barrier.

9599 IDIOPATHIC NEONATAL HEPATITIS: DISCORDANCE IN MONOZYGOTIC TWINS. (E.)

Lough, J. (McGill U., Montreal, Canada) and J. D. Metrakos. Canad. Med. Ass. J. 96(18):1258-1261, 1967.

Two pairs of monozygotic twins, discordant for idiopathic neonatal hepatitis, are described. In the first pair, both were born slightly jaundiced; 1 was discharged because of the transient nature of the jaundice. The other was admitted at 8 days and later discharged when the bilirubin level decreased to 7.8 mg%; he was readmitted at 3 mo., and at laparotomy the bile ducts were normal and patent; liver biopsy showed multinucleated cells, scattered areas of necrosis, large pale liver cells, and bile thrombi consistent with neonatal hepatitis. The bilirubin level continued to decline without treatment. At 16 mo. he was operated on for repair of a large right inguinal hernia. The jaundice at this time had cleared completely and the total bilirubin was 0.25 mg%. He was entirely well when last seen at 15 yr. In the second pair, 1 was born well. The other was admitted at 7 wk. because of progressive jaundice since 5 days of age, associated with pale stools and dark urine. Open liver biopsy and operative cholangiography showed a patent biliary tree. Biopsy showed giant cell transformation, extensive hematopoiesis, bile stasis in hepatic cells, and canaliculi consistent with neonatal hepatitis. She was readmitted at 8.5 mo., after 6 mo. of steroid therapy in another study, and appeared healthy and nonjaundiced. A follow-up needle biopsy showed minimal changes of neonatal hepatitis and a third biopsy was entirely normal. All liver function tests were normal at 15 mo., and steroids were discontinued. She was well when last seen at 4.5 yr. of age. Family histories of both pairs were noncontributory, with no history of liver disease in near relatives. There was no consanguinity in either family. There was at least a 97% chance that each of the pairs was monozygotic. The discordance is evidence against viral infection acquired prenatally as the primary cause of idiopathic neonatal hepatitis. Immaturity of the intracellular bilirubin excretory pathoway is suggested as a cause of this disease.

9600 ACTIVITY OF ALDOLASE, PHOSPHOHEXOISOMERASE AND ALKALINE PHOSPHATASE IN THE SALIVA AND BLOOD OF PATIENTS AFFECTED WITH EPIDEMIC HEPATITIS. (Rus.)

Daragan, V. G. (Lugansk City Hosp., USSR), L. K. Popova, N. U. Petrischeva and V. S. Paranich. Klin. Med. (Moskva) 45(3):76-79, 1967.

In 20 healthy controls, aldolase ranged from 2.0-10.0 (av. 6.0) conventional U in the blood, and 2.0-8.0 (av. 5.0) in saliva; phosphohexoseisomerase was absent, but alkaline phosphatase ranged from 0.4-4.0 (av. 4.0) Bodansky U in blood, and 0.4-5.0 (av. 4.5) in saliva. In 58 patients with viral hepatitis, the range of values for blood and salivary aldolase was 10 conventional U or
less in 8 and 22 subjects, resp.; 11-20 conver
tional U in 28 and 23 subjects; 21-30 conventi
U in 17 and 8; and 31-40 conventional U in 5 s
jects for both blood and saliva. Therefore,
during an attack of viral hepatitis, salivary
aldolase apparently increases somewhat later t
that of blood. During recovery, blood aldolas
decreased to normal in 16 of 22 subjects, whil
salivary aldolase remained significantly highe
than normal; during recovery, such liver funct
tests as bilirubin, thymol turbidity, mercuric
chloride, and the Takata-Ara and Weltmann reac
tions returned to normal earlier than salivary
aldolase. Alkaline phosphatase was normal in
both blood and saliva for all but 1 of 15 pat
with viral hepatitis with a severe form of the
disease, whose blood alkaline phoaphatase increased to 50 U, but whose salivary enzyme was
normal. Blood phosphohexoseisomerase activity
was slightly elevated in only 5 of the 58 pat
but this enzyme, independently of the time and
severity of the disease, was absent in saliva

9601 RHEOHEPATOGRAPHY IN THE ASSESSMENT
THE DYNAMICS OF ACUTE AND RESTORATI
PERIODS OF INFECTIOUS HEPATITIS. (Rus.)

Kirzhner, L. S. (Inst. Virusol., Acad. Med. S
Moscow). Klin. Med. (Moskva) 45(3):86-91, 19

The instrument was connected to a 2-channel
electrocardiograph, and the following paramet
were defined: QX, the rheographic index; TA,
max. amplitude; QY, time periods; and TA/AY,
elasticity of the vascular wall (which av. 1.
normals, with a range of 0.9-1.1). In most o
the 116 patients (63 men, 53 women; most of w
were 15-40 yr. old) with viral hepatitis (mil
form, 68; moderately-severe form, 39; prolong
form, 7), the hepatic blood circulation was d
turbed during the entire period of hospitaliz
especially in patients with a prolonged form
the disease. Changes in the rheohepatogram d
the first wk. of jaundice included a decrease
in amplitude of the curve with a reduced rheo
graphic index; this was found in 86.2% of the
patients and was maintained in 92.3% of these
during convalescence. The QX segment during
acute period was at the upper limits of norma
or was increased to 0.14-0.16 sec. (in 15 hea
normals it was 0.06-0.12 sec.); the TA segmen
was decreased, but rarely was reduced below t
lower limit of normal. Segment QY was decrea
and reached 0.42-0.44 sec. (in healthy normal
it was 0.44-0.54 sec.); if it was low in the
first wk. of jaundice, it became normalized a
the time of recovery. In 10-12% of the patie
segment QY could not be determined. The stre
coefficient (TA/AY) during the initial jaundi
period was less than 0.9, and at recovery it
mained low in 40% of the patients (it was 1.0
normal individuals). In 11 of 116 the rheohepatogram was normal at the time of hospital
tion for the disease, and abnormal at release
5 it was normal during the entire period of o
servation. Consequently, the rheohepatogram
normalized at time of release in only 9 (7.7%

patients. Three mo. after release, 41 of 84
ents were considered cured, and 26 of the 41
a normal rheohepatogram. Only 1 of 43 pa-
ts with an incomplete cure had a normal rheo-
atogram. At 6 mo. after release, 70 of 84 pa-
ts were cured, and 64 of 70 had normal rheo-
hic indices; the rheohepatogram remained ab-
al in all of 14 convalescents with an in-
lete cure (7 of the 14 had a prolonged form
he disease). In all outpatients, the bili-
n, aldolase, transaminase and mercuric chloride
results were normal. Two of 7 patients with
olonged form of the disease were rehospitalized
residual symptoms. Rheohepatography is recom-
ded for use both in special situations and in
hospital in order to facilitate better observa-
of convalescents. Two case histories are
ented in detail.

2 THE SIGNIFICANCE OF SERUM AMMONIA LEVELS IN EPIDEMIC HEPATITIS. (Rus.)

, M. V. (Leningrad Pediat. Med. Inst., USSR).
. Med. (Moskva) 45(3):79-85, 1967.

d ammonia and glutamine were determined in
ealthy subjects and in 166 patients (pre-
nantly women; 15-65 yr. old) with viral
titis (28 of whom had a mild form of the
ase; 106, a moderately-severe form and 32 a
re form). The ammonia conc. in healthy sub-
s ranged from 0.02-0.06 mg% and from 0.025-
mg% in viral hepatitis patients. The am-
a content was dependent upon the severity of
disease and the length of time the patient
hepatitis. A normal ammonia conc. was found
ost patients with a mild form of the disease,
4% of the moderately-severe cases at the peak
he disease, and in 43% with severe hepatitis.
highest ammonia conc. (up to 0.36 mg%) was
d in 13 patients with hepatic coma, 11 of
died. In several of the severe cases, the
nia conc. returned to normal at termination
he disease, while in 8% of the mild-moderately
re cases, the ammonia conc., was somewhat
ated (up to 0.07-0.10 mg%); this paralleled
erbation of the disease and increase in
dice. In most cases, the ammonia level was
alized during convalescence; the ammonia level
what exceeded normal in several cases with a
nic, periodic form of the disease. The in-
sed ammonia content during convalescence could
icate that the pathologic process in the liver
not completely terminated. The serum glut-
e content in healthy individuals varied from
-2.3 mg%. The glutamine content in those with
ild form of the disease fluctuated from 1.8-
mg% in 62.5% of the patients who had a normal
nia conc.; increase in ammonia conc. generally
alleled an increase in the glutamine level.
s pattern was also found in moderately-severe
acute forms of the disease. In 50% of those
a chronic and protracted form of the disease,
increase in ammonia conc. was not accompanied
an increase in glutamine conc. A parallel
rease in both ammonia and glutamine occurred
st frequently among those with severe disease.
During convalescence, the glutamine conc. either increased or reduced, signifying either synthesis or utilization of glutamine. Exacerbation was usually accompanied by an increase in the ammonia level (in all 7 cases) and a simultaneous increase in the conc. of glutamine (6 of 7 cases). Ammonia metabolism was most disturbed in 13 patients with hepatic coma, who had a high serum ammonia from 0.12-0.36 mg%. The ammonia conc. increased most frequently in fatal cases, and decreased with recovery. The glutamine conc. usually did not increase as much as did ammonia. Study of 54 patients with obstructive jaundice revealed an ammonia level of 0.03-0.10 mg%. In patients with cholecystitis and cholelithiasis, abatement of the disease process and decrease of jaundice was not accompanied by a change in ammonia conc. There was no increase in the ammonia conc. in patients with malignancy during the progressive exacerbation of this condition. The glutamine conc. ranged from 1.875-2.700 mg%, and did not always parallel the ammonia conc. Thus, a certain specificity of the changes in ammonia and glutamine conc. in blood occurs in viral hepatitis, in contrast to jaundices of other etiology. Three cases histories are presented in detail.

9603 THE BIOLOGICAL IMPLICATIONS OF THE HOYT-MORRISON REACTION. IDENTIFICATION OF AN AGGLUTINATING GAMMA-GLOBULIN. (It.)

Ortona, L. (Sacred Heart Catholic U., Rome), A. Barbarino and L. Quintiliani. Boll. Ist. Sieroter. Milan. 45(11-12):571-576, 1966.

Sera from 3 patients with viral hepatitis and positive Hoyt-Morrison test reactions of 1:64, 1:64 and 1:32, resp., were fractionated on a cellulose column and subjected to immunoelectrophoresis on agar gel and double immunodiffusion, as well as the original Hoyt-Morrison technic. In all 3 cases, the Hoyt-Morrison reaction was demonstrable in serum fractions containing γ-G globulins and was not demonstrable in any other fraction or combination of fractions, including γ-M.

9604 THE ROLE OF HEMAGGLUTINATING ANTIBODY ACTIVITY IN POST-HEPATITIS PATHOLOGY.

(It.) Balsano, F. (U. Palermo, Italy), G. Pitucco, L. Salerno, E. Cucchiara and A. Musca. Boll. Soc. Ital. Biol. Sper. 42(24):1880-1882, 1966.

Following apparent recovery from acute viral hepatitis, a number of patients in whom the Hoyt-Morrison hemagglutination test became positive during the period of elevated serum transaminase levels required 2-4 mo. for normalization of the test. In still others, the test remained positive for observation periods of more than 6 mo., during which they developed chronic or recurrent, presumably nonviral, hepatitis accompanied by structural damage to the liver. In all of these cases, as in a corollary study employing monkeys, the degree of positiveness increased sharply after each "cytolytic wave" reflected by increased serum transaminase levels, suggesting that the abnormal antibody activity followed necrotic liver damage, rather than preceding it. Accordingly, it is suggested that the same agent may be responsible for the "cytolytic wave" in question, whether it occurs in the presence of viral hepatitis or as part of a post-hepatitis syndrome which induces additional liver damage.

9605 THE VALUE OF γ-GLOBULIN PROPHYLAXIS IN THE CONTROL OF HEPATITIS. (Ger.)

Renger, F. (Carl Gustav Carus Med. Acad., Dresden, Germany) and A. Bley. Z. Ges. Hyg. 13(2):138-142, 1967.

Human γ-globulin was obtained from donor and placental blood; antibodies were conc. 10-fold during fractionation; that obtained from donors (about 3000) presented a polyvalent preparation with a high titer of immune bodies. This, briefly, was the procedure in the preparation of γ-globulin used in Eastern European countries to immunize 300,000 children. The incidence of hepatitis had previously been about 78.5/1000. Among those immunized the av. incidence was 18/1000. Similar reports are given with respect to other pathologies against which immune bodies are present in the γ-globulin fraction. The risk of transfusion hepatitis was reduced from 2.5-3.4% (2-5 transfusions) and 7% (more than 10 transfusions). The percent reduction (difficult to compute) was at least 50% in the fewer earlier transfusions and with no increased risk in additional later transfusions. Furthermore, among those treated with γ-globulin who still contracted hepatitis, the disease was anicteric, mild and of a shorter duration. The i.v. dose of γ-globulin for prophylaxis was 0.02-0.04 ml/kg. When danger of infection is great 0.04-0.12 ml/kg is inj. i.v. A second inj. 6 mo. later again restored passive immunity.

9606 TREATMENT OF PROTRACTED CONTINUING HEPATITIS IN AMBULATORY PATIENTS.

(Ger.) Krosch, H. (Martin Luther U., Halle-Wittenberg, Germany) and W. Teichmann. Deutsch. Z. Verdau. Stoffwechselkr. 26(5-6):222-228, 1966.

The continued care of ambulatory hepatitis cases presents a difficulty much appreciated by workers in this field: The accurate, or even fairly accurate, assessment of the current state of a protracted case by means of clinical and routine laboratory tests is problematical. Liver biopsies, the one basic test, cannot be taken as often as needed. One requirement, not well met at present, is the ability to recognize relapses early. Of 230 hepatitis cases followed during hospital treatment of at least 6 wk., and ambulatory control up to 2 yr. with a group of chemical tests chosen as the most indicative. These tests, the number of patients in the group who showed increased values, and the % of the group were: 1) SGOT, 140 (61%); 2) SGPT, 103 (45%); 3) thymol test, 93 (40%); 4) serum bilirubin, 40 (17%);
5) no increase in the values in any of these t
55 (24%). Although these tests were admin. ev
10 days for at least 90 days to each patient,
55 or 24% showed no increase in values even ir
the early stages. However, some patients with
elevated values in all 4 tests furnished resul
for analysis of these factors during the entir
course of the disease. Increases in serum bil
rubin and the thymol test occurred sharply wit
the first 10 days, the latter reflecting in-
creased γ-globulin conc. SGPT reached a peak
20-30 days and SGOT in 30-40 days; the serum
transaminase levels declined gradually, reachi
normal values between 60 and 90 days. The dec
in serum bilirubin and thymol were much more
abrupt. Three cases were individually plottec
a graph during 90 days after onset of the dise
In 1 instance, the thymol test showed a small
distinct peak on the twentieth day followed ir
5 days by a rise in SGOT and SGPT, both reachi
a peak at 40 days (a total rise for each of ab
160 U). These secondary peaks represented a
relapse. Another case showed a small peak in
the thymol test (still abnormally elevated) at
40 days; although the thymol test declined, th
slope was slight; SGOT and SGPT had fallen to
normal values (below 40 and 30 U) at 30 days,
their values began to turn upward with increas
slope; this patient was in transition to chron
hepatitis.

9607 QUANTITATIVE DETERMINATION OF CONJUG BILE ACIDS IN SERUM ACUTE HEPATITIS.

(E.) Frosch, B. (U. Heidelberg, Germany) and
H. Wagener. Nature (London) 213(5074):404-40
1967.

After extraction of serum with hot ethanol, th
bulk of the lipids was removed by distributior
ether, ethanol, heptane and water. Conjugatec
bile acids were separated by thin-layer chroma
raphy. This simultaneously removed bilirubin
and the remaining lipids from the bile acid sp
Quantitative determinations of the different c
jugates were made, in the presence of silica g
with sulfuric acid, salicylic aldehyde, sulfur
acid and acetic acid, and ethyl acetate, aceti
acid anhydride and sulfuric acid. Added pure
conjugated bile acids were recovered at approx
100% levels; sensitivity was 0.5 µg/ml serum.
this method serum from normals contained no co
jugated bile acid. Alterations in serum conju
bile acid were studied in a case of acute hepa
titis, with an interval of 8 days between the
of jaundice and the first determination of bil
acids. Initially there was a considerable in-
crease in most conjugates caused mainly by in-
creased conc. of taurochenodeoxycholic acid ar
glycochenodeoxycholic acid. The initial value
the total conjugated bile acid was 330 µg/ml
serum; final value, 40 µg/ml. Alterations in
conc. of serum bile acid were accompanied by
similar alterations of conc. of serum bilirubi
and serum enzyme. The latter were normal at t
end of observation, although bile acids were s
elevated. These observations were confirmed i

:hers with acute hepatitis. Conc. of total
n conjugated bile acid after normalization of
rubin and transaminases were 12-130 µg/ml
n. Liver biopsy specimens of these cases still
ed histological abnormalities. It is con-
ed that determination of conjugated bile
in serum during the course of liver disease
uperior to other tests of abnormal liver cell
:ion.

DIAGNOSIS AND CLINICAL PICTURE OF
ANICTERIC FORMS AND FORMES FRUSTES OF
EMIC HEPATITIS IN TUBERCULOUS PATIENTS. (Rus.)
erman, A. M. (Min. Health, Moldavian SSR,
inev). Ter. Arkh. 39(1)63-66, 1967.

ng the period 1961-1964, of 130 patients with
ve pulmonary tuberculosis and viral hepatitis,
16, more than 35 yr. old) had the exhausted
nicteric form and 48 had the pronounced icteric
of hepatitis; 482 tubercular patients with no
r pathology served as the controls. Clinical
toms, present in 67 of 82 patients, lasted
than 10 days in 12 persons and 11 days-2 mo.
5. A slight increase in serum bilirubin (more
1 mg%) was found in 72 of 82; of these, 66
the direct reaction for bilirubin. Aldolase
vity was normal in 7 of 80 patients, slightly
eased (9-15 U) in 30 of 80, and significantly
eased in approx. 50%of the patients. The
reliable test for differential diagnosis was
rmination of SGPT activity; this was increased
ll of the patients (to mostly more than 100-
U) and 53 of 60 patients tested had an in-
sed activity of SGOT. The least reliable
s (due to alterations among the control sub-
s) included the Takata-Ara reaction, which
positive in two-thirds of the patients; the
min-globulin index, which was less than 1 in
of the patients; and reduced excretion of
uric acid (after admin. of sodium benzoate)
3% of the patients. RBC were increased in
atients, and a decreased RBC sedimentation
was found in 36 persons. In 49 of 82 patients
illness was of a chronic nature, and normaliza-
of biochemical indices occurred after 6 wk.;
e was no normalization in 32 patients. The
difficult differential diagnosis was found
ases of toxic-allergic liver reactions develop-
from admin. of antitubercular agents.

SERUM FREE FATTY ACIDS IN CHILDREN
WITH VIRAL HEPATITIS. (Ger.) Spahn, U.
Child. Clin., Jena, Germany). Klin. Wschr.
0):530-533, 1967.

m free fatty acids were determined in 26
dren (2-9 yr.-old) with viral hepatitis after
-hr. fast for a total of 133 titrimetric
urements; 16 of these children had at the
t of the disease been placed on a liver diet
in fat, but rich in carbohydrate and protein.
addition of fat to the diet usually occurred
he twenty-eight stationary treatment. The
r 10 were fed on a slightly modified normal diet which from the beginning contained butter fat. The patients had mild to moderately-severe cases of the disease; 3 had anicteric courses. Among the clinical symptoms, and as liver enlargement; jaundice (range of serum bilirubin, 1.51-6.67 mg%) and bilirubinuria, which most of the children had, were the anicteric, inexplicable, greatly increased transaminase values (SGPT above 800 U). Children (12) with nonhepatic disorders such as diabetes, and adiposity comprised the controls. From the outset there were no significant differences in the serum free fatty acid values between those on the liver diet and those on the diet containing fat. A significant difference did exist between those with hepatitis and those without hepatitis at the beginning. By the twentieth day of treatment the difference between the hepatitis and nonhepatitis patients was no longer significant; the serum free fatty acid conc. had decreased in the hepatitis patients, and began to approach the normal values. On the twenty-first day of treatment the serum values were practically normal. At this time the transaminase levels, which had been high, also had fallen to the normal range. The decrease in serum free fatty acid conc. and the fall in serum transaminase levels are parallel in children recovering from viral hepatitis.

9610 EXPANSION OF THE DIET IN BOTKIN'S DISEASE IN CHILDREN. (Rus.) Kuzntsova, S. V. (Odessa Med. Inst., USSR). Pediatriia 46(3):69-72, 1967.

A total of 282 children (1-16 yr. old) with viral hepatitis (milk form, 209; moderately severe, 59; severe, 14) were treated with either Diet Number 5 (Group 1, 200 children; this consisted of 38-82 g protein, 20-50 g fats, and 250-500 g carbohydrates, for a total of 1322-2778 calories, depending upon age) or the expanded diet (Group 2, 82 children; this consisted of 50-95 g protein, 50-90 g fats and 230-450 g carbohydrates, for a total of 1540-2990 calories, depending upon age); the latter did not exacerbate the clinical course of the disease and biochemical indices were the same as in controls. In Group 2 the appetite, although improved, was diminished for a prolonged period of time in 27 patients. In Group 1, the av. duration of jaundice was 10.3 days for the mild form of the disease, and 24.3 days for the moderately-severe form; values for Group 2 patients were 10.7 and 22.7 days, resp. An increase in wt. was found in 87% of the Group 1 children and in 75% of those in Group 2. Pyoderma occurred in 12% of those in Group 1 and in 3.6% of those in Group 2; intercurrent diseases were found in 12% of Group 1 children and 14% of those in Group 2, while residual symptoms were found in 75.5% and 59.8%, resp. The β-lipoprotein level in Group 2 was increased during period 1 of the disease (at admission); it decreased slightly during period 2 (second wk. of jaundice) and continued to normalize during period 3 (at release); however, in most of the patients it was still above normal values (above 35 U). A similar pattern of β-lipoprotein conc. was also noted in Group 1. In Group 2, cholesterol was increased (180-250 mg%) in 70.5% of the children during Period 1 and in 64.7% during Period 2; in Group 1, cholesterol was decreased (less than 120 mg%) in 56.6% and 50.3%, resp. (normal values were 120-170 mg%). Hypercholesteremia (more than 250 mg%) was found in a similar number of patients in both groups. The differences which have been noted occurred chiefly in the mild form of the disease. At release, abnormal cholesterol conc. were found in 40.8% of those in Group 2 and in 44.4% of those in Group 1. Hyperlipidemia (greater than 850 mg%) in Group 2 was found in 25 of 58 children during Period 1 of the disease, in 11 of 49 during Period 2 and in none of 55 during Period 3; in Group 1, hyperlipidemia was found in 37% of the children during Period 1 of the disease, in 21.3% during Period 2 and in only 2 children during Period 3.

9611 SIGNIFICANCE OF HUMAN SERUM TRANSFUSION IN VIRAL HEPATITIS TRANSMISSION. (Rus.) Pille, E. R. (Sanit.-Epidem. Station, Leningrad, USSR), F. G. Itselis and M. N. Kulakova. *Zh. Mikrobiol*. 44(2):108-111, 1967.

Antiinfluenza serum (amount used indicated in brackets) from donors who previously had influenza was given to 8106 adults and children (162,765 ml) in 1963, to 12,585 (255,750 ml) in 1964 and to 3443 (83,615 ml) in 1965. No correlation between the morbidity of hepatitis and the use of antiinfluenza serum was found until 1963, at which time, during April-June, cases were registered among the recipients of Serum Series Number 2364. This serum was given to 28 children, of whom 10 (35.7%) had the icteric form of hepatitis; however, the real morbidity may have been greater. Among adults, only 1 case of hepatitis could be definitely recorded for this serum; another 2 cases among adults may not have received this serum. Chronic cholecystitis was diagnosed in 1 of 15 donors several mo. after blood donation. It is thus possible that this person had the anicteric form of hepatitis and became the source of infection. During the period August, 1964-January, 1966, 796 patients were hospitalized for hepatitis, and 328 (188 adults, 140 children) of these had previously received antiinfluenza serum. An anamnesis obtained in 252 of 328 (145 adults, 107 children) patients showed that 13 children (up to 7 yr. of age) and 5 adults (over 50 yr. old) had received antiinfluenza serum 2-6 mo. before the onset of the disease. However, analyses of this serum revealed no association between these infections and inoculation of this serum. Simultaneously, 11 of 18 patients received blood and plasma, and this could possibly have been the source of infection. It is concluded that, with the present methods of donor investigation, the risks of serum hepatitis are not great, but cannot be completely excluded.

9612 EPIDEMIOLOGY OF VIRAL HEPATITIS. (Ger.) Červenka, J. (Epidem. Microbiol. Res.
Inst., Bratislava, Czechoslovakia). *Z. Ges.*
13(2):133-138, 1967.

The incidence for the 9-yr. period 1957-1965
235/100,000. The max. morbidity in the Czech
regions was in the 7- and 8-yr. age groups,
whereas in the Slovak regions it occurred in
the 5- and 6-yr. bracket. Max. morbidity occ
in November for individuals up to the age of
There was no special seasonal incidence of he
titis in those older than 30. For the whole
country the incidence in first-yr. group was
approx. 1/1000, rising to 8/1000 at 8 yr., th
falling to 6/1000 at 12 yr., to 2/1000 at 24
and to 1/1000 at 50 yr.

9613 EXPERIENCES WITH RAPID ENZYME TESTS
THE EARLY DETERMINATION AND EPIDEMI
CONTROL OF VIRAL HEPATITIS. (Ger.) Woratz,
(Annaberg Hosp., Germany), F. Hajduk and P. Mi
Z. Ges. Hyg. 13(2):143-147, 1967.

In a group of 2000, 87 persons became ill wit
hepatitis during a period of 6 mo. Screening
tests, the determination of 3-4 serum enzymes
were instituted when 60 had developed symptom
of hepatitis. Routinely SGPT, fructose-1,6-d
phosphatealdolase (ALD) and LDH were determin
by the rapid color tests. The speed with whi
ALD rose as infection began and the parallel
changes in the enzyme level with the course o
icteric hepatitis made this test especially u
ful. Screening children in a school with onl
2 tests, 89 were found to have increased seru
enzyme levels; 12 showed an increase in SGPT
well as ALD, 77 showed only an increase in th
latter; of the whole group (89, ALD-positive)
some had a mild course of hepatitis generally
indicated by lesser serum elevation of ALD an
others had a more severe course. It is signif
that the ALD test was sensitive enough to differentiate mild anicteric cases. Graphing th
courses of ALD and LDH tests for an identical
group of 22 subjects for a total of 6.5 wk. s
a gradually decreasing serum conc. of ALD in
latter half of the interval with only 2 mildl
erratic courses, whereas the serum conc. of L
in more than 50% of the cases rose in the lat
half of the interval to exceed previous peak
values.

9614 USE OF MODERN SCREENING TESTS IN THE
EPIDEMIOLOGIC CONTROL OF HEPATITIS.
(Ger.) Anders, G. (Humboldt U., Berlin) and
C. Wagenknecht. *Z. Ges. Hyg*. 13(2):131-133,

The technic involved in these tests (determin
of serum enzyme levels) has been described in
previous paper. The rapid color tests are us
because they are inexpensive, rapid, require
simple apparatus, can be used in the field by
persons with little training and are so devis
that its sensitivity is greatest in the regio
of slightly increased enzymatic activity. Th
sensitivity is of the order of that of the

rophotometer. The tests were first employed
hepatitis epidemic to screen the people in
llages and 4 collectives; in addition, all per-
in contact with cases of the illness were
ed 2 times/wk. for 3 wk. Almost 10,000 enzyme
rminations were made on 2820 persons, 116 cases
e disease were discovered; these were ex-
ed clinically and all had hepatitis. This
ted to 4.1% of those examined; their dis-
tion was 5 in the early stages of jaundice,
closed by SGOT and by LDH, 1 by SGOT only and
LDH only; of 25 in the early anicteric stage,
re diagnosed by SGOT and LDH, and 10 by SGOT
78 in an anicteric course, 8 by SGOT and
2 by SGOT only, and 68 by LDH only; 4 not
d, 2 by SGOT and LDH, 2 by SGOT only; of 4
chronic hepatitis, 2 were diagnosed by both
by LDH only. Of 9558 persons tested, 140
positive by the rapid color tests or an in-
ce of 1.5%. Among these, the disease took
icteric course in 69.4% of the cases. All
ns with elevated serum enzyme conc. in these
should immediately undergo a medical examina-
These enzyme color tests are sufficiently
ostic for screening tests.

THE EPIDEMIOLOGY OF EPIDEMIC HEPATITIS.
(Rus.) Skolubovich, G. V. (Blagovesh-
k Med. Inst., USSR). Zh. Mikrobiol. 44(2):
34, 1967.

1955-1964 standard epidemiological studies
carried out on 1570 foci of viral hepatitis;
clinical-laboratory and epidemiological
nations were performed on 250 foci for 2-12
Healthy contacts (more than 2800) were either
ned daily or no less than 2 or 3 times/wk.
al of 220 patients with the "fruste" and
eric forms of hepatitis were isolated during
nitial 3-5 days after onset of the disease;
days before the appearance of jaundice, 178
nts were isolated. During an observation
d of 2 mo. 70 patients were found with the
te" form of hepatitis; in a 3-mo. observation
d 81 were found, in 6 mo., 51 and in 12 mo.,
In a control group (1570 foci) examined once
7-10 days, usually only patients with
lice were detected. Approx. 20% of 220 pa-
s with the "fruste" form of hepatitis were
ource of infection in healthy persons, and
ersons were infected from 32 patients with
nicteric form. In the foci observed by the
r, 48% of the patients had the "fruste"
of hepatitis, but in Leningrad this percentage
ot exceed 6. The incidence in Sakhalin and
was no better. This showed that many pa-
s with the anicteric or "fruste" form of
itis remained undetected, and this is one
e essential causes of the high morbidity in
hepatitis. A study of patient infection
ases of the disease showed that in the last
days of the incubation period they were the
e for (actual) contact and parenteral in-
ion. It was additionally discovered that
nts with the "fruste" form in whom the pro-
had a lingering chronic course with periodic
exacerbations were a source of infection. Under the activity of γ-globulin the "fruste" form of hepatitis appeared in persons infected by contact, and these could be the source for further infection.

9616 LYSOSOMAL INJURY IN MURINE VIRAL HEPATITIS. (E.) Datta, D. V. (Harvard Med. Sch., Boston, Mass.), W. A. Jones and K. J. Isselbacher. Gastroenterology 52(5):828-836, 1967.

Studies on the role of lysosomal injury in the initiation and propagation of hepatic cell necrosis have given inconsistent results, although concurrent lysosomal injury and hepatic cell damage has been demonstrated. In evaluating the occurrence of lysosomal damage and its possible role in the production of hepatic cell necrosis in viral hepatitis the authors iniated an anatomical, histochemical and biochemical study using the MHVS strain of virus. It was shown that lysosomal enzyme alteration may be detected as early as 24 hr. following MHVS infection, before hepatic necrosis could be observed by light microscopy. There was an increase in acid phosphatase activity as well as in the lysosomal enzymes in the unsedimentable or soluble fractions, although there was no significant change in the total lysosomal enzyme activity. These changes persisted for 7-14 days, gradually returning to normal. Early changes were best detected by histochemical methods or by these methods in combination with biochemical technics. The latter methods alone did not show a significant increase of acid phosphatase until 36 hr. Increases in β-glucuronidase and acid ribonuclease were not seen until 48 hr. These changes progressed for 7 days, returning to normal thereafter. Such early changes in the lysosomes prior to evidence of necrosis suggest that lysosomal injury may have a role in initiation or perpetuation of hepatic necrosis subsequent to MHVS viral infection.

9617 THE EFFECT OF CARBOHYDRATE-ENRICHED DIETS ON VIRUS HEPATITIS IN THE MOUSE. (E.) Zuckerman, A. J. (Guy's Hosp. Med. Sch., London) and I. Macdonald. Guy Hosp. Rep. 116(1): 33-37, 1967.

Weanling albino mice (10-15 g) were separated into 3 groups. One group was fed a normal, balanced diet; the other 2 groups were fed a diet containing 12% Ca caseinate, 81% carbohydrate, 5% salt mixture, and 2% dried yeast with added vitamins A and D; the carbohydrate supplied to 1 group was corn starch and to the other sucrose. Half the mice in each group were inj. i.p. with 0.1 ml of 6.3×10^{-5} of mouse hepatitis virus 3 (MHV3), and half of the mice were inj. with 1×10^{-2} of MHV1. After 12 wk. the animals were killed and weighed. The liver was excised, its wet wt. determined and portions fixed and prepared for histological examination; the remaining liver was dried in a vacuum dessicator, and the fat extracted. Collagen in the fat-free liver was measured. Some mice received virus inoculation at the beginning of the experiment; others received the virus after 6 wk. on the resp. diets. The mean body wt. of mice infected with MHV3 was lower throughout the experiment than the mean wt. of comparably uninfected groups on the control diet and on the starch diet. Mice on a sucrose diet tended to gain wt. less quickly than animals fed on the starch or the control diet. Infection with MHV 1 did not cause parenchymal cell necrosis, but when the animals were placed on a deficient diet some degree of necrosis of the liver ensued. Infection with MHV 3 resulted in marked necrosis of the parenchyma on the normal diet, with increasing severity of necrosis on the starch diet and almost complete hepatic necrosis on the sugar diet. No increase in either reticulum or collagen was noted in the livers of any group.

TREATMENT OF INTRACTABLE ASCITES BY RE-
INFUSION OF UNMODIFIED AUTOGENOUS ASCITIC
. (E.) Pearlman, D. M. (Albert Einstein
Med., Bronx, N. Y.) and G. Duremdes. Surgery
:248-254, 1967.

patients with cirrhosis and intractable as-
were treated by i.v. infusion of their un-
ed autogenous ascitic fluid. All had been
regimen which included Na restriction, di-
cs of the thiazide group and aldosterone
onists. In addition, most received 1 or more
e following: salt-poor albumin, mercurial
tics, abdominal paracentesis, adrenal cortical
ids, aminophylline and mannitol. Four of
atients had such voluminous ascites that
ration and oral intake of food and liquids
compromised. Patients were allowed their
ar diet and fluids without restriction; they
given diphenhydramine (50 mg 4 times a day)
he dose of thiazide diuretic and aldosterone
onist which they had been receiving was con-
d. All patients tolerated the procedure
The only adverse reaction was moderate
ia in 3 patients; this symptom was controlled
antihistamines and acetylsalicylic acid with-
iscontinuation of the infusion. The amount
citic fluid reinfused ranged from 6.3-26.0
s. Reinfusion of ascitic fluid produced good
sis and improvement in general condition in
f the patients. Two illustrative case re-
are presented in detail.

THE CORRELATION OF CLEARANCE AND DIS-
TRIBUTION OF COLLOIDAL GOLD IN THE
AS AN INDEX OF HEPATIC CIRRHOSIS. (E.)

e in hepatic function, 13 patients; and 4)
e decrease in hepatic function, 10 patients.
patient was scanned with ^{131}I-rose bengal
olloidal ^{198}Au in doses varying from 0/2-0.45
th each dose individually calculated and
ted so as to maintain a peak counting rate
00 counts/min. with either material; inter-
between scans ranged from 10-14 days, so as
nimize any residual effect of the previous
Clearance measurements were conducted using
en 25-50 µc of ^{131}I-rose bengal or colloidal
. From the colloidal ^{198}Au scans and clear-
it was found that the combination of factors
olonged clearance time, spleen visualization
erihilar accumulation was almost invariant
ses of severe liver impairment; these char-
istics decrease in incidence with moderate
liver impairment, and the indications of proliferation about the hilus and decreased peripheral distribution were very useful in identifying the early minimal effects of this disease. Alterations in the distribution of the radioactive material demonstrated *in vivo* what was predicted by identification of arteriovenous anastomoses in cirrhosis; these alterations were paralleled throughout by the reduction of clearance of colloidal ^{198}Au, which was consistent with the existence of arteriovenous shunts.

9637 THE LEVEL OF ANTIDIURETIC HORMONE IN THE BLOOD OF PATIENTS WITH LIVER CIRRHOSIS AND ASCITES. (Rus.) Berezov, V. M. (Inst. Ther., Moscow). Ter. Arkh. 39(3):20-23, 1967.

The Jeffer's method for determination of antidiuretic hormone level in blood was not sufficiently sensitive in 5 healthy persons (23-35 yr. old) and in 5 patients (31-46 yr. old) with hepatic cirrhosis but no ascites, and conc. of antidiuretic hormone was considered zero. In 23 of 31 patients with hepatic cirrhosis and ascites (in 16 of 31 it was combined with edema of the lower extremities), the conc. of antidiuretic hormone in blood varied from 2.0-10.4 µU/ml of serum pituitrin "P" and was zero in 8 of 31 patients; the av. antidiuretic hormone level was 4.5 ± 0.58 µU of serum pituitrin "P". The postnecrotic form of hepatic cirrhosis was predominant in patients with (24) or without (3) ascites. There was no correlation between the antidiuretic hormone in blood, the degree of liver pathology, the activity of the cirrhotic process and the amount of ascites. Nineteen of 31 (in whom the characteristic symptom was oliguria) were resistant to commonly-employed diuretics; in 7 of 19, the Reberg test was normal, while the antidiuretic hormone level ranged from 0-10.4 µU. Hyponatremia was found in 11 patients with edema, in 8 of whom the antidiuretic hormone level varied from 4-10.4 µU/ml; instead of polyuria, they showed oliguria. The causes of antidiuretic hormone secretion in patients with liver cirrhosis and ascites, such as changes of osmotic blood pressure and decrease in intravascular vol., are discussed. An increase in the antidiuretic hormone blood level together with other factors plays a dominant role in the pathogenesis of ascites.

9638 ACTIVITY OF FIBRINASE IN LIVER CIRRHOSIS AND CHRONIC HEPATITIS. (Rus.) Malyarovsky, V. N. (Inst. Med. Radiol., Acad. Med. Sci., Moscow). Ter. Arkh. 39(1):61-62, 1967.

Fibrinase activity was measured in 17 patients with hepatic cirrhosis (Group 1) and in 10 patients with chronic hepatitis (Group 2), while 20 healthy normals served as controls. In Group 1 the av. fibrinase activity was 72%, in Group 2 it was 94%

and in controls, 100%; the tolerance of plasma to heparin was 1335 sec., 890 sec. and 556 sec., resp.; blood prothrombin activity was 76%, 92% and 100%, resp.; plasma recalcification time was 172 sec., 120 sec. and 94 sec., resp.; and fibrinolysis time was 228 min., 270 min. and 300 min., resp. No parallel relationship was found between fibrinase activity and other indices of blood coagulation. In Group 1 there was an inverse relationship between fibrinolytic activity and fibrinase activity. In most patients with increased fibrinolytic activity there was a more pronounced decrease in fibrinase activity, especially in patients with hemorrhagic diathesis.

9639 BETA-GLUCURONIDASE ACTIVITY IN THE LYSOSOME FRACTION OF NORMAL AND CIRRHOTIC HUMAN LIVER.

(It.) Giglio, F. (U. Palermo, Italy), L. Pagliaro, S. Le Moli, P. Citarrella, A. Notarbartolo and G. Migneco. Fegato 12(4):478-487, 1966.

β-Glucuronidase activity was studied in lysosome suspensions obtained from 8 normal subjects and from 18 patients with cirrhosis (12 with severe hepatic failure and massive ascites; 6 with moderate failure and without ascites). As compared to cirrhotic patients with severe hepatic failure, those with moderate failure presented less free enzyme activity (av. 26.8 against 31.9 μmoles x 10^3 of phenolphthalein released per mg of lysosome protein), higher total activity (av. 111.3 against 55.8 μmoles x 10^3 of phenolphthalein), and markedly lower free:total enzyme activity ratio (av. 23.44% against 57.94%), the last parameter being statistically significant. As compared to normal subjects, patients with moderate hepatic insufficiency presented greater free enzyme activity (av. 26.8 against 6 μmoles x 10^3 of phenolphthalein), the same total enzyme activity, and significantly higher free:total activity ratio (23.44% against 5.04%). No correlation was observed between free:total activity ratio and γ-globulins; slight correlation was seen between free:total activity ratio and blood albumin levels; the free:total activity ratio was inversely proportional to the serum pseudocholinesterase content. It is concluded that the increase in the free:total enzyme activity ratio observed in patients with cirrhosis is proportional to the degree of functional hepatic insufficiency.

9640 CORRELATION OF SERUM L-PHENYLALANINE-SENSITIVE ALKALINE PHOSPHATASE, DERIVED FROM INTESTINE, WITH THE ABO BLOOD GROUP OF CIRRHOTICS.

(E.) Stolbach, L. L. (Lemuel Shattuck Hosp., Boston, Mass.), M. J. Krant, N. I. Inglis and W. H. Fishman. Gastroenterology 52(5):819-827, 1967.

In this study, 139 patients with hepatic cirrhosis were found to have serum levels of L-phenylalanine-sensitive alkaline phosphatase which correlated with ABO blood groups, suggesting that genetic factors may play a role in determining the extent to which enzymes of intestinal orig
contribute to the elevation of serum alkaline
phosphatase. The physiology underlying the
elevation of the enzyme in the serum of these
patients is poorly understood at present. No
correlation could be made with such factors as
increased portal pressure as manifested by
esophageal varices or the pressure of ascites.
The significantly higher incidence of L-phenyl
alanine-sensitive alkaline phosphatase to tota
alkaline phosphatase ratios of greater than 0.
in cirrhotics with Blood Types B and 0 was fou
to exist in patients with normal levels of to
alkaline phosphatase, as well as in patients
elevated levels. Higher mean levels of total
alkaline phosphatase were found in patients wi
Blood Type 0 than in those with Type A. These
elevations were due partly to higher mean leve
of the L-phenylalanine-sensitive isoenzyme.
intestinal origin of a major part of the L-phe
alanine-sensitive alkaline phosphatase is sug
by starch gel electrophoresis of the serum in
which a slow-moving band was inhibited by L-p
alanine, migrating to the location of purifie
intestinal alkaline phosphatase. The results
the present study support a genetic mechanism
controlling the serum levels of L-phenylalani
sensitive alkaline phosphatase and, in turn,
alkaline phosphatase. These results contribu
as well, to a better interpretation of the si
nificance of hyperphosphatemia.

9641 NEGATIVE LIVER FUNCTION TESTS IN CA OF PORTAL CIRRHOSIS.

(It.) Maldac
(Riuniti Hosp., Rome), A. Beni and C. Pingi.
Gazz. Int. Med. Chir. 72(9):779-787, 1967.

Among 370 patients with confirmed hepatic cir
rhosis observed over the past few yr., 17 (4.
showed no significant serum protein or colloi
lability alterations. Jaundice was present i
6 of the 17 patients. Diabetes mellitus was
present in 8 of the 17 (48%) patients, althou
insulin treatment was required in only 1.
Esophageal varices and neurological manifesta
were present in 6 and 9, resp., of the 17 pat
Electrophoresis was performed in 10 patients
was normal in 5; 3 showed an increase in bot
α_2- and β-globulins, while 2 showed an increa
α_2- and β-globulins, resp. γ-Globulin level
normal in all 10 patients. Glycoprotein mea
ment in 1 patient revealed an absence of γ-g
lins. The sulfobromophthalein test was posi
in 3 of 5 patients. Alkaline phosphatase an
transaminase levels, prothrombin time, as we
as serum levels of free cholesterol and chol
terol esters were altered in most of the patients. Three illustrative cases are descri
The authors conclude that the apparent discr
between clinical and laboratory data in thes
patients with cirrhosis is due either to ass
diseases (diabetes, for example) or to parti
biochemical disturbances, such as lack of in
of γ-globulins.

SPATIAL RELATIONSHIPS BETWEEN HEPATO-
CYTES AND SINUSOID ENDOTHELIAL CELLS IN
HEPATIC CIRRHOSIS. (It.) Cavalli, G. (U.
na, Italy), F. B. Bianchi and G. Bacci.
o 13(1):55-65, 1967.

ron microscope studies were conducted on
ic tissue (obtained with the Menghini biopsy
e and fixed in Palade's soln. containing
se) from 10 patients with hepatic cirrhosis.
paces of Dissé were abnormal in 1 or more
e following ways: the endothelial cells
d a continuous outer layer; a finely granular
ance, irregularly arranged, formed a layer
rying thickness immediately beneath the en-
lial cells (this layer resembled a basal
ane but appeared in discontinuous tracts);
llar structures were more frequent than in
l spaces; the hepatocyte surface proximal
e space of Dissé appeared to be without
villi, forming raised extensions; reduction
e space between hepatocytes and endothelial
for more or less long tracts caused direct
ct between the 2 types of cells (this condi-
being facilitated by the absence of micro-
and the presence of such uniting structures
smosomes and zonula adherens). The authors
ude that these morphological changes are
y to influence the normal exchanges between
helial cells, circulating blood, and hepato-
.

SIGNIFICANCE OF BLOOD SERUM ENZYME AND
LIVER TISSUE INVESTIGATION FOR THE
SMENT OF THE ACTIVITY OF THE PROCESS IN
IC CIRRHOSIS. (Rus.) Bondar, Z. A. (First
w Med. Inst.), S. D. Podimova and V. B.
arevskii. Ter. Arkh. 39(1):54-60, 1967.

ctivity of glutamine-alanine transaminase in
(in U/ml) and in punch biopsy material (in
issue) in 34 patients with hepatic cirrhosis
g the active stage of the disease (Group 1)
7.6 and 13,800, resp.; during the inactive
of the disease (Group 2) it was 33 and
0, resp., and in 16 patients with chronic
itis (Group 3) it was 30 and 16,643, resp.
oup 1 the activity of glutamine-aspartic
aminase in serum and punch biopsy material
3.8 and 30,500, resp.; in Group 2, it was
and 27,410, resp., and in Group 3, 39 and
0, resp. The decreased activity of glutamine-
ne transaminase activity appeared to be a
quence of less parenchyma in far-advanced
osis of the postnecrotic or mixed type, and
evelopment of dystrophic changes in the
ocytes. The activity of phosphohexoseisomerase
rum (in μg of fructose) and in punch-biopsy
ial (in mg of fructose/g tissue) in Group 1
2 and 60.4, resp., in Group 2, 42.9 and
resp., and in Group 3, 41 and 44, resp.
ity of alkaline phosphatase in serum (in
sky U) and in puncture-biopsy material (per
tissue) was 7.1 and 14.3, resp., in Group 1;
oup 2 it was 6.5 and 9.6, resp., and in
3, 2.4 and 4.7, resp. The increase in glutamine-alanine, glutamine-aspartic transaminase and phosphohexoseisomerase activity in liver tissue indicates pronounced regenerative and inflammatory processes in developing hepatic cirrhosis, while their increase in blood sera indicates rapidly-developing cirrhosis. Two case histories are presented in detail.

9644 PROGRESSION OF ACUTE HEPATITIS TO POSTNECROTIC CIRRHOSIS. (E.) Schaeffer, J. W. (U. Cincinnati Coll. Med., Ohio), L. Schiff, E. A. Gall and Y. Oikawa. Amer. J. Med. 42(3): 348-358, 1967.

This process was documented in 5 patients by serial histological observations. In none was the source of hepatitis known; alcoholism, hepatotoxins, and drugs were not implicated. The hepatitis was assumed to be of viral etiology in view of the characteristic histological and clinical features. In none were the onset of illness and the preicteric period abrupt or unusually severe. Malaise, weakness, and complaints of upper gastrointestinal tract involvement were the foremost symptoms. The most obvious findings were deep jaundice and a moderately enlarged liver; the spleen was palpable in 3. Jaundice reached a peak during the fifth wk. and continued for 16 wk. Two experienced a relapse during the course of subsiding jaundice during the first mo. after illness. Three received steroid therapy during the first episode of jaundice; in 2, complete remission of activity was observed at 10 and 14 mo., resp., despite development of cirrhosis; in the third, the clinical symptoms and biochemical abnormalities responded, but there was no interruption in the progressive hepatocellular necrosis leading to death in hepatic coma within 3 yr. In the 2 not treated with steroids, 1 recovered within 4 mo., the other died in hepatic coma after 4 yr. At the height of jaundice, the serum total bilirubin was 13.4-44 mg% (av. 26.1); there was a constant elevation of SGOT compared with SGPT. Significant hypoalbuminemia and elevated serum globulin levels were observed. Serum turbidity and flocculation tests were consistently abnormal. Of the 3 surviving patients: in 2 serum transaminases and bilirubin values are normal and there was no BSP retention; values were minimally abnormal in 1.

9645 FREE FATTY ACIDS AND THE ACTIVITIES OF LIPOPROTEIN LIPASE AND POST-HEPARIN ESTERASE IN LIVER CIRRHOSIS. (Ger.) Fabian, E. (Charles U., Prague), L. Kučerová, A. Štork and J. Šponarová. Z. Ges. Inn. Med. 22(3):74-77, 1967.

Twenty patients with hepatic cirrhosis and (16 cases with Laennec's cirrhosis, 3 with biliary cirrhosis, and 1 person in hepatic coma) furnished fasting blood samples for the determination of serum levels of lipoprotein lipase, postheparin esterase activity; and free fatty acid conc. The same parameters were measured in 20 healthy individuals. The av. values for the 16 patients with Laennec's cirrhosis compared to those of the 20 healthy individuals: Lipoprotein lipase, 20.73 U in Laennec's cirrhosis, 29.88, in normals; post-heparin esterase (μM Ca laurate) 0.49 in Laennecs, 7.42 in normal males, 3.94 in normal females; free fatty acids (μEq/liter) fasting plasma 892 Laennec's, 491 normal. Rise in free fatty acids (μEq/liter) after heparin inj., 521 in Laennecs, 846 in normals. Total fat mg% 695 Laennecs, 842 in normals. Total cholesterol in mg% 191 in Laennecs, 232, in normals. Total protein g%, 7.83 in Laennecs, 7.46 in normals. The free fatty acid levels were significantly increased in Laennecs cirrhosis over those in healthy persons; lipoprotein lipase was significantly reduced in Laennec's disease as was also post-heparin esterase. The individuals with biliary cirrhosis showed considerable variation in the same categories. There was a doubling of free fatty acid after heparin inj. so that post-heparin esterase was significantly increased. Lipoprotein lipase was increased in hepatic coma.

9646 PHYSIOPATHOLOGY OF JAUNDICE IN HEPATIC CIRRHOSIS. (Fr.) Pavel, I., S. Campeanu, C. Dumitrescu and H. Bonaparte. Arch. Franc. Mal. Appar. Dig. 56(3):121-140, 1967.

Various factors determining or influencing jaundice in hepatic cirrhosis were studied in 9 patients with cirrhosis but with no overt jaundice and in 3 frankly jaundiced cirrhotic patients. Hemoglobin formation and av. age of RBC were measured by radioactive methods; the effects of controlled induced hyperhemolysis, induction of increased hypersideremia, and the action of carbaminoylcholine upon the BSP clearance were studied for definite evidence of correlation with jaundice. Optical microscopy of liver biopsies were also done, as well as studies of the effects of methyl-17-testosterone upon the liver parenchyma. Of these, hemoglobin formation antagonized jaundice whereas the other tests increased bilirubin formation. The extent and interaction of factors in the patient made précise determination of the onset and severity of jaundice difficult to predict. When hemoglobin formation is predominant in hepatic cirrhosis, jaundice is not evident. Jaundice in portal cirrhosis cannot be explained by mechanical obstruction caused by sclerosis and compression or obliteration of bile ducts. However, logical factors in other types of cirrhosis may cause jaundice, such as 1) imbalance between the production and elimination of bile pigments, 2) acquired hyperhemolysis such as that due to chronic malaria or intercurrent infection, 3) changes in hepatic arterial blood flow, 4) a functional obstruction, such as a stone, in the extrahepatic biliary ducts.

9647 THE EXCRETION OF COPROPORPHYRIN ISOMERS I AND III IN DISEASES OF THE LIVER AND BLOOD. (Ger.) Clotten, R. (U. Freiburg/Brg., Germany) and A. Doyen. Z. Klin. Chem. 5(2): 54-59, 1967.

The normal urinary excretion of coproporphyrin
was established in 40 healthy subjects of both
sexes. In order to preclude latent diseases,
especially those of the liver, these controls
were given a series of tests before determinat
of coproporphyrin. These tests were for serum
transaminases, hemoglobin, RBC, hematocrit, WB
differential count, and serum protein electro-
phoresis. The pathological cases tested compr
12 virus hepatitis, 1 acute yellow liver atrop
18 liver cirrhoses of different degrees of
severity and different etiologies, 12 severe F
deficiency anemias, 4 panmyelopathies, 11 con-
genital achrestic (hypoplastic) anemias, 4 hem
lytic anemias,of different genesis, 1 Cooley's
anemia, 2 leukemias, 1 Hodgkin's disease, and
severe bleeding anemia. Coproporphyrins were
extracted or separated by high voltage electro
phoresis immediately from 24-hr. urine specime
and analyzed by spectrophotometer. Isomers we
determined by paper chromatography. Normal ur
nary coproporphyrin excretion in middle age wa
between 41 and 182 μg/day for men with a mean
of 88.6 ± 30.2 μg, and 43-135 μg/day for women
with a mean of 70.8 ± 28.1 μg. Healthy men an
women had a predominant urinary excretion of c
proporphyrin III (64.8% and 62.2%, resp.). In
orders of the liver, nonalcoholic cirrhosis wa
accompanied by a prevalance of coproporphyrin
alcoholic cirrhosis caused an increase of copr
porphyrin III. Coproporphyrin I predominated
in only a few cases of hepatitis; most cases c
clinical hepatitis showed a distribution of th
isomers similar to the normal. Among the hepa
cases only 2 had a greater than normal excreti
of coproporphyrin. The normal excretion of co
porphyrin in the hepatitis patients (except 2)
was in line with the other values in laborato
tests (within the normal range). Most of the
cirrhosis patients showed 24-hr. coproporphyri
excretion above 200 μg (av. 335 μg/24 hr.); a
few were in the normal range. The highest cop
porphyrin conc. excreted in the urine occurred
Fe-deficiency anemias (mean 404 ± 41 μg). In
panmyelopathy the amount observed was 388 ± 1
μg/day; congenital hypoplastic (sideroachresti
and hemolytic anemias presented about the same
picture (308 ± 141 and 300 ± 223/24 hr.).

9648 PATHENOGENESIS OF HEPATIC COMA. (Ge
Müting, D. (First Med. U. Homburg/Sa
Germany), H. Reikowski, W. Eschrich and H. Bu
Verh. Deutsch. Ges. Inn. Med. 72:649-652, 196

Various biochemical determinations were made
116 patients. One was a case of decompensate
hepatic cirrhosis, with bleeding of esophagea
varices, following which, over a considerable
period of time, there occurred hepatitis the
bilirenal syndrome, obstructive jaundice, and
intoxication. Among the 116 patients, 84 were
in Terminal Stage III and 32 in Stages I and
of hepatic coma; a long observation period wa
possible in 90 of these cases. The same meas
ments were made in 50 normal subjects. Free
α-amino nitrogen in the cerebrospinal fluid o

normal subjects av. 0.8 mg%; of those with tic disease without coma, 1.4 mg%; of those recoma, 2.8 mg%; and in hepatic coma, 3.7 mg%; ne same order the serum levels of α-amino- ogen were, resp., 4.2, 4.8, 6.0 and 7.2 mg%. ne same order, the cerebrospinal fluid values free phenols were 0.60, 1.2, 1.85 and 2.8 mg% the serum levels for free phenols, resp., 0.92, 1.85, 2.92 and 4.0 mg%. Ammonia in the rospinal fluid av. 31 μg% in the normal, g% in those with hepatic disease without signs oma, 230 μg% in those with precoma and 480 in those with coma; the corresponding blood ls were 62, 160, 280 and 500 μg%, resp. , among these 3 parameters these were in- sing conc. in blood and cerebrospinal fluid increasing severity of hepatic disease. ysis tended to restore the free phenols and nia content almost to normal (from 6 mg% to t 1.6 mg% for the free phenols and from over ug% of ammonia down to 180 mg% in the serum) the values became immediately elevated follow- dialysis of more than 48 hr. The height of the nia conc. did not necessarily bring about nopathologic syndromes. A patient in the oma stage with decompensated alcoholic cir- is had been on a protein-free diet and neo- n therapy so that the blood ammonia level was al following infusion of ammonia-decreasing tances; the mental difficulties of the patient red up at the same time. A lapse in diet ed a renewed rise in ammonia conc. to the ious levels but without the appearance of nopathology; the blood and cerebrospinal levels ree phenols had not increased. The free phenol and the conc. of metabolic byproducts of ntaining amino acids may be important in ng brain damage in hepatic disease. Indican ndole derivatives appear to play only a minor in the pathogenesis of hepatic coma.

EXPERIMENTAL LIVER INJURY IN THE RHESUS MONKEY: I. EFFECTS OF CIRRHOGENIC AND ETHANOL. (E.) Cueto, J. (West Virginia Ctr., Morgantown), N. Tajen, E. Gilbert and Currie. Ann. Surg. 166(1):19-28, 1967.

observation for 6 mo. while on a diet of na monkey chow, 9 male Macaca mulatta monkeys divided into 3 groups: Group 1 (3 animals), ved a high-fat, low-choline, low-protein diet, n addition, they were given ethanol (5 g/kg, nes a wk. by gavage, diluted 1:1 with bi- onate soln.); Group 2 (3 animals) were fed na chow and, in addition, received ethanol avage with 1 g choline added as a supplement, twice/wk. protein supplement; Group 3 (2 als) were fed a high-fat, low-choline diet out ethanol. One animal was followed as a rol on a standard diet of Purina monkey chow ad libitum. At the end of an 8-mo. period, ficant liver damage and elevation of portal is pressure were produced by a low-choline, -fat diet. Oral ingestion of alcohol did not avate the injury produced by this diet, nor t significantly alter hepatic function or structure in animals fed a normal diet with protein and choline supplements. Admin. of ethanol was associated with the development of gastritis in several animals and, in both groups in which it was given, alcohol tended to depress appetite and diminishethe total caloric intake of the animals. These preliminary results suggest that hepatic cirrhosis, portal hypertension and abnormal portosystemic communications similar to those seen in human cirrhosis can be produced by the cirrhogenic diet in the Rhesus monkey; additional research is needed to determine how similar to human cirrhosis this experimental injury may be. The chronic liver disease and portal hypertension produced in this manner may furnish a good experimental model to investigate the causes and treatment of portal cirrhosis and its complications.

9650 COLLAGENOLYTIC ACTIVITY AND COLLAGEN RESORPTION IN EXPERIMENTAL CIRRHOSIS. (E.) Morrione, T. G. (Long Island Coll. Hosp., Brooklyn, N. Y.) and J. Levine. Arch. Path. (Chicago) 84(1):59-63, 1967.

Cirrhosis was induced in male Sprague-Dawley rats (175-200 g body wt.) by inhalation of CCl_4; in addition, α-naphthylisothiocyanate cirrhosis was induced in 50 rats (100-125 g wt.) by feeding 1 g α-naphthylisothiocyanate to 1 kg powdered laboratory chow. The collagenolytic activity of extracts of rat livers was significantly decreased when hepatic damage was induced by CCl_4 or α-naphthylisothiocyanate. Elevation of enzyme activity was observed during the phase of active collagen resorption in recovery from CCl_4 cirrhosis. Partial hepatectomy (65%-75%) was accompanied by resorption of collagen and increased enzyme activity in reversible CCl_4 cirrhosis, whereas in irreversible cirrhosis neither of these changes was seen. Human liver showed collagenolytic activity similar to that which was seen in rat liver. Liver glycogen content ranged from 0.49%-3.38% (net wt.), av. 2.90% in normal liver. Both hepatotoxic agents as well as subtotal hepatectomy depressed hepatic glycogen content, and glycogen levels rose in all animals during recovery from hepatic injury. Normal liver showed a value of 21.7% of dry fat-free wt.; all forms of hepatic injury as well as subtotal hepatectomy lowered the percentage of dry fat-free wt. to as little as 15.9%; these lowered values showed a rise during the recovery stages. Max. enzymatic activity was found in the "light mitochondrial" fraction, indicating lysosomal origin. A 7-day fast resulted in a 35% loss of body wt. (in 3 rats, av. body wt. declined from 268 to 175 g), a 72% loss of liver wt. (from 14.9 to 4.2 g), a 3-fold increase in percentage of collagen in the liver (from 0.11% to 0.37% wet wt.), with an actual resorption of 4.3% of total hepatic collagen. However, during this period collagenolytic enzyme activity declined to a level 25% below normal. In both forms of cirrhosis which were studied, no cellular alterations could be correlated with the changes in enzyme activity in the various stages of induction or reversal of cirrhosis.

Both CCl_4 and α-naphthylisothiocyanate produced a depression of hepatic enzyme activity.

9651 EFFECT OF PORTACAVAL SHUNTS ON LYMPH FLOW IN THE THORACIC DUCT. EXPERIMENTS WITH NORMAL DOGS AND DOGS WITH CIRRHOSIS AND ASCITES. (E.) Orloff, M. J. (Harbor Gen. Hosp., Torrance, Calif.), B. Goodhead, C. W. O. Windsor, M. E. Musicant and D. L. Annetts. *Amer. J. Surg.* 114(2):213-221, 1967.

The primary hemodynamic lesion in cirrhosis is hepatic venous outflow obstruction; much evidence has been accumulated which indicates that both the increased production of lymph and the formation of ascites in experimental and human cirrhosis are produced by elevation of intrahepatic pressure which results from outflow obstruction. Accordingly, the capacity of end-to-side and side-to-side portacaval shunts to reduce intrahepatic pressure was evaluated by measuring the effects of these procedures on pressure and lymph flow in the thoracic duct of 50 dogs. The latter were divided into 5 groups: Group 1, 10 normal dogs; Group 2, 20 normal dogs with portacaval shunt; in 15, an end-to-side anastomosis was performed, and in 5 a side-to-side shunt; Group 3, 6 dogs in which congestive cirrhosis, portal hypertension and massive ascites were produced by ligation of the hepatic veins; Group 4, 6 dogs subjected to an end-to-side portacaval shunt after congestive cirrhosis, portal hypertension and massive ascites were produced by hepatic vein ligation; Group 5, 8 dogs which underwent a side-to-side portacaval shunt after production of congestive cirrhosis, portal hypertension and ascites by ligation of the hepatic veins. Hepatic vein ligation resulted in massive ascites, which av. 4.0 liters, portal hypertension, which av. 208 mm of saline soln., a mean 13-fold increase in thoracic duct lymph flow and a mean elevation of thoracic duct pressure which was almost 3 times the normal level. The end-to-side portacaval shunt reduced the high rate of lymph production and the elevated pressure significantly, but a 5-fold increase in lymph flow and an approx. 2-fold elevation of thoracic duct pressure persisted. The side-to-side portacaval shunt lowered thoracic duct pressure to normal in every dog, and either abolished the excessive lymph formation or markedly reduced the rate of lymph production. These findings indicate that the side-to-side portacaval shunt is more effective than the end-to-side anastomosis in overcoming intrahepatic hypertension and decompressing the obstructed hepatic vascular bed. These results represent an important consideration in the selection of surgical therapy for intractable cirrhotic ascites, and may have some bearing on the effects of portacaval shunts on nutrition of the hepatic parenchyma.

9652 FAMILIAL PIGMENTARY INFANTILE CIRRHOSIS. (Fr.) Nezelof, C. (Necker Hosp., Paris), J. M. Watchi, P. Ganter and A. Brault. *Presse Med.* 75(9):451-456, 1967.

Two sisters with familial pigmentary cirrhosis
were studied during their brief infancies. Th
elder had in the first few wk. suffered coryza
laryngitis; at 3.5 mo. digestive troubles nece
sitated hospitilization during which ascitis a
cells with black pigmentation were found; the
patient weighed 6200 g, had an enlarged abdome
and varices in the epigastrium; the liver and
spleen were not enlarged; RBC were 2,490,000/m
35% hemoglobin, 8200 WBC with normal different
count; the ascitic fluid was poor in protein;
there was no proteinuria and no reducing bodie
in the urine. Wasserman and Bordet tests of t
parents were negative. The patient lapsed int
a coma and died 3 days after admission. Autop
disclosed a small liver weighing 120 g, showin
multiple, light-colored nodules, 2-15 mm in
diameter; these nodules were much softer than
parenchyma of the liver. The biliary tract an
gallbladder were normal; the spleen was a litt
enlarged but appeared functionally normal; no
esophageal varices were noted; other than an
ulcerous laryngitis no other gross pathologica
conditions were found. The histology of the l
revealed general cirrhosis; dense fibrosis, po
in cells and practically free of inflammatory
types was found both in peri- and intralobular
sites with spans of liver tissue in contact wi
the fibrosis showed a tendency to form canals
peppercorn structures, with enlargement of bil
canals. Abundant pigment deposits were noted
the cytoplasm of liver cells. This pigment wa
in 2 forms: 1 of large particles, ochre or
brown, looking somewhat like granules of hemos
erin; the other form showed very fine granules
of the same color; the pigment granules were
isotropic in polarized light; they were not, o
very slowly, bleached by hydrogen peroxide; th
Fe was ferric; protein was found in conjunctio
with it. All other tests such as for bilirubi
and lipopigments, among others, proved negativ
The Fe-pigment granules occupied the biliary p
of the hepatic cells grouped about or in the
neighborhood of the biliary canaliculi. Histo
study revealed islands (especially in the nodu
of regenerating hepatic tissue. Some changes
found in other orggans, but no trace of Fe deposition was found in any other organ than the
liver. The younger sister had a different ear
medical history; she died at the age of 8 wk.
Autopsy revealed an ascitis, and a small cirrhotic liver, absolutely comparable to that of
older sister. The histologic lesions were ide
cal in every respect. This anicteric disease
of rapid fatal course is probably a congenital
metabolic disease.

9653 TREATMENT OF LIVER CIRRHOSIS WITH ANTIMETABOLITES. (Fr.) Terrase, J.
S. Moinade and D. Rigal. *Presse Med.* 75(13):6
654, 1967.

A group of 21 alcoholic cirrhotics were treate
with antimetabolites; another group of 22 cirrhotics were treated by the classical method;
of the first group received cyclophosphamide

) mg/day); 8 were given 6-mercaptopurine (6-MP,
-200 mg/day); 1 case was given mannomustine
2 others received cyclophosphamide and then
P. All received antibiotics. Of the 22
ated by the classical method, 4 showed ameliora-
n and 11 were unchanged; of the 21 treated with
imetabolites 10 were improved and 3 were un-
nged. The reduction of inflammatory states
e to the antimetabolites) promoted healing.
ticosteroid anti-inflammatory therapy was also
in. Because of the relatively few cases
lied, and the well-known variations encountered
cases of cirrhosis, definite conclusions cannot
drawn. The impression remains, however, that
se treated with antimetabolites ran an easier
rse and showed a greater degree of recovery
n those without them; 6-MP seemed to be more
icient than cyclophosphamide.

9662 DIAGNOSTIC SIGNIFICANCE OF THE REFLUX OF THE CONTRAST MEDIUM INTO THE PANCREATIC DUCT IN OPERATIVE CHOLANGIOGRAPHY. (Rus.)

Pautkin, Y. F. (Patrice Lumumba U., Moscow). Vestn. Rentgen. Radiol. 42(1):48-51, 1967.

Reflux of contrast preparations into the pancreatic duct at surgical cholangiography was found in 43 (33%) of 132 patients. Contrast preparations (diodone, acetrizoic acid, and others, as 25% soln.) was admin. by puncture of the bile duct in 21, through the vesicular duct in 109 and by a combination of both in 2. Of 60 patients without any pathological changes of the terminal portion of the common bile duct and pancreas, 20 showed reflux of the contrast preparation. In the remaining 72 patients with pathological changes of the distal part of the common bile duct and pancreas, 23 exhibited reflux. The latter was found most frequently in the presence of the inflammatory process in the pancreas (11 of 22), and rarely in the presence of bile stones, spasms or stenosis. Reflux at the time of the first photograph (at the moment of termination of contrast admin.) was found in 30 of 43, and later at the time of the second photograph (after 3 min.) it disappeared; in 13, reflux was evident at both photographs (in 9 patients with and 4 without pathologic changes). Of 43 patients with reflux, residual pressure was increased in 28; of 89 patients without reflux, increased residual pressure was noted in 73. Therefore, reflux of contrast preparations into the pancreatic duct should not be evaluated as a sign of pathological changes of the distal portion of the common bile duct and pancreas.

9663 PSEUDO-OBSTRUCTION FOLLOWING POST-CHOLEDOCHOTOMY CHOLANGIOGRAPHY. (E.)

Ginzburg, L. (Beth Israel Med. Ctr., New York, N. Y.), A. Geffen and I. H. Friedman. Ann. Surg. 166(1):83-90, 1967.

During 1962-1966, 71 choledochotomies for calculus disease were performed at Beth Israel Hospital; in 56, an immediate post-choledochotomy T-tube cholangiogram was performed, using 35% Diodrast as a contrast medium. In 30 of 56 cases, the contrast medium did not immediately appear in the duodenum; in 4, such passage was seen on films taken 10-20 min. later. No passage occurred in 26 patients. In 24 of the 26 patients, there was no evidence of either calculus or any other intraluminal obstruction and the ducts were not re-explored. In 2 cases re-exploration was made because of irregular filling of the distal duct associated with obstruction; in 1 case an additional small calculus was removed, but even after this, contrast material did not enter the duodenum. In the second patient, re-exploration was negative, but the contrast medium again failed to enter the duodenum. In all 56 patients, regardless of the findings in postcholedochotomy radiography, postoperative cholangiography 10-14 days later showed free passage into the duodenum, and no evidence of calculus or other abnormal findings. It is thought that failure of radio-opague mat to enter the duodenum during postoperative cholangiography results from spasm or edema at the choledochal (Boyden's) sphincter or the du denal wall itself, and not at the sphincter of Oddi. The relationship of reflux into the pan creatic duct (which occurred in 2 of 56 cases) to spasm of the choledochal and ampullary (Odd sphincters is also discussed.

9664 STUDIES ON THE ORIGIN OF INCREASED SERUM AMYLASE FOLLOWING INFUSION OF THE BILE DUCT WITH AN ENZYME-CONTAINING SOLUTI

(Ger.) Heinkel, K. (U. Erlangen-Nuremberg, Germany) and H. Spanknebel. Z. Gastroent. 5(2 94-96, 1967.

Ten rats (140-230 g) had the common bile and pancreatic duct catheterized and the catheter ligated close to the duodenum. The bile duct was ligated near the liver hilus in 6 animals that an infusion only into the pancreas was po sible. The supernatant of a suspension of 0.5 dried pancreatin in 25 ml of 0.9% NaCl after c trifugation was used for infusion at a definit pressure with a known amount of fluid. The amylase activity of this fluid broke down 105. of starch (Heinkel and Spanknebel); 3 of these 6 rats received a betacholine inj. i.p. 30-40 min. after beginning of infusion. Before and during the infusion, at 15-min. intervals, the amylase blood level was measured. The blood amylase conc. rose from an av. equivalent of 4 at the beginning to 9.2 g% in 30-45 min. Inj. i.p. of betacholine at this point caused an ex cessive rise in blood amylase conc. The infus pressure was between 20 and 30 mm Hg with an a inflow of 2.4 ml in 15 min. into the pancreas which was edematous before inj. of betacholine Edema disappeared when betacholine was inj.; the inj. caused a rise in the blood amylase equivalent from 4.9 g% on the av. to 39.5 g%. The blood amylase conc. was also increased by vagal stimulation (no values given) during the time of infusion. Betacholine caused flow of fluid (possibly containing excess amylase) fro interstitial spaces back into blood stream. out the ligature on the bile duct close to the hilus the infusion fluid passed rapidly throug the liver parenchyma into the blood.

9665 OCCLUSION OF THE BILE DUCT AND ENZYME ACTIVITY IN THE SERUM. (Ger.

Schultz, C. (City Hosp., Remscheid, Germany) and E. Schmidt. Klin. Wschr. 45(3):162-163,

In a patient with protracted cholestasis and a secondary chronic inflammation, complete obstr tion of the bile duct occurred as a complicat due to inflammatory stenosis of the papilla. The obstruction was relieved by a T-drain whi furnished the opportunity to study the relati of increased pressure in the bile ducts to ser levels of some enzymes by clamping off the T-

most rapid and greatest response to a decreased
e drainage with a pressure increase in the
e duct from 10 to over 30 cm H_2O was in the
um level of glutamic dehydrogenase which in-
ased to 3 times resting level or 200% within
r. after the pressure rise. Serum levels of
aline phosphatase, SGOT, SGPT, and a bilirubin
c. showed little increase, if any, above nor-
values. Some enzymes had moderate increases
serum levels as a result of increased biliary
ssure; these were aldolase, malic dehydrogenase,
phosphoglycerate kinase; altogether, the
um conc. of 10 enzymes was determined. Others,
h as leucine aminopeptidase and sorbitol de-
rogenase, had minimal variations from the
ting values. These findings corroborate the
ue of determining glutamic dehydrogenase levels
serum in the early diagnosis of biliary ob-
uction.

6 EXPLORATION OF THE COMMON BILE DUCT
WITH VAN BUREN SOUNDS. (E.) Meyerowitz,
R. (Albert Einstein Coll. Med., Bronx, N. Y.).
r. *J*. *Surg*. 113(6):861, 1967.

Van Buren type urethral sound is widely used
Britain for exploration of the common bile
t, and is said to be more advantageous in this
than is the Bakes' dilator employed in the U.S.
Van Buren sound allows the surgeon a better
d, and gives him more control of the instrument.
also affords full contact with the entire length
the duct, whereas the Bakes' dilator can con-
t only one segment at a time. In addition to
sound's exploratory use, it simplifies trans-
denal sphincterotomy by allowing the surgeon
cut down on it while it is held firmly in place
h its tip protruding through the ampulla of
er.

7 THE ESTABLISHMENT OF CHOLEDOCHODUO-
DENOSTOMY WITH THE AID OF A SPECIAL AP-
ATUS. (Rus.) Ryneiskii, S. V. (Fac. Clin.
g., 2nd Moscow Med. Inst.) and Iu. I. Morozov.
rurgiia (*Moskva*) 43(2):115-117, 1967.

189 choledochoduodenostomies, a mechanical
ure was used on 9 patients (8 women, 1 man;
76 yr. old); 6 of these had mechanical jaundice,
4 had purulent cholangitis. All of the pa-
nts had a preliminary cholecystectomy. Using
NZhKA apparatus, the technic was as follows:
lodochotomy was made at the extreme end of the
denum by a small incision through which the
mon bile duct was sounded, concretions were
racted and the opening in Vater's papilla was
lored; the intestinal wall adjacent to the
ning in the common bile duct was punctured
the suturing branch of one-half of the ap-
atus was pulled through the opening on the
e of Vater's papilla; the branch of the other
f of the suturing apparatus was introduced
ough the puncture in the duodenum. The walls
the common bile duct and duodenum were sutured
h 2 rows of clamps, and simultaneously the
lumen of the anastomosis was formed. The apparatus was returned to its initial position, the branches were separated and the apparatus removed. The two openings in the common bile duct and duodenum after imposing of the anastomosis were blended into one opening. The openings which conducted branches of the apparatus were sutured with 2 rows of nodular silk sutures. The anastomosis was almost entirely located in the retroduodenal space and it usually included the pancreatic part of the common bile duct. Contraindications for use of this apparatus are at the high position of the liver, at narrow and deep surgical approaches of introduction of branches of the apparatus into the duodenum and, especially, into the common bile duct. Each patient had an X-ray 4-7 days after operation. A severe postsurgical period, complicated by pneumonia, cardiovascular insufficiency and cystitis, was noted in only one 76-yr.-old female patient. All patients were released in good condition an av. of 23 days after surgery. One case history is presented in detail.

9668 ETIOLOGY OF INTRAHEPATIC CYSTS OF BILE DUCTS. (Ger.) Ehrhardt, G. (Friedrich Schiller U., Jena, Germany) and R. Schiewe. *Zbl*. *Allg*. *Path*. 110(2):119-126, 1967.

A 45-yr.-old female patient underwent cholecystectomy with revision of the bile duct, for obstructive jaundice with simultaneous pancreatitis. Concretions were not found in the gallbladder or in the duct. Histologically, there was chronic cholecystitis with a decreasing pericholecystitis. On the seventeenth postoperative day cholangiography was performed through the T-drain revealing an empty space in the right hepatic lobe the size of a hen's egg. It was deemed a cyst of the intrahepatic bile duct when the serological test for *Echinococcus* proved negative. The postoperative course was uneventful. The patient was readmitted 8 mo. later with intermittent obstructive jaundice. Upon re-operation the patient was found to have a fist-sized adenocarcinoma in the portal region of the liver, the origin of which could not be determined. The patient died of fulminating tumor 3 wk. later. Found at autopsy were: In the right lobe of the liver, a liver cyst 8 x 8 x 9.5-cm reaching the liver capsule; thickness of the cyst wall 3-5 mm. Cyst contents were crumbling bile solids and a solitary pigmented cholesterol-lime stone; the walls and roof of the cyst were infiltrated by the tumor with full destruction. A right-sided intrahepatic bile duct terminated in the floor of the cyst with also a broad connection to the right hepatic duct proper. At the juncture of the right and left hepatic ducts there was an open abscess perforating the portal region into the duodenum, involving also the pylorus of the stomach with the bed of the gallbladder. The tumor invaded the common bile duct with destruction and complete obliteration of the lumen and infiltrated the hepatoduodenal part of the small omentum walling up the distal 3-cm of the bile duct. Carcinoma tissue in the pancreas partially blocked the duct. Other metastases were in para-aortal lymph nodes, pleurae and both lungs. Small and large knots of metastasing tissue were in the liver. Histologically, the cancerous tissue was a mature solid adenocarcinoma. The cyst wall showed cylindrical epithelial cells in places; no smooth muscle fibers were to be seen but there were abundant neural fibers, and mucous glands. Only 5 such cases have been previously reported in the literature.

9669 TRANSHEPATIC DRAINAGE OF THE BILIARY TRACT. (Fr.) Pomidori, A. (Fac. Med., Naples, Italy). Lyon Chir. 63(1):21-26, 1967.

Following biliary surgery (removal of calculi, sphincterotomy, biliodigestive anastomosis, etc.), a 23-cm polyethylene tube (usually 1-1.5-cm diameter) with a slightly curved end was introduced through the common bile duct into the right hepatic duct and then through the hepatic parenchyma, with an external opening in the lateral thoracic or axillary area. After edema or dilatation of the bile ducts subsided and tonus returned to normal (8-18 days later) the drain was removed. Three patients were treated in this way and are described briefly. Transhepatic drainage of this type is recommended particularly for patients undergoing surgery of the papilla of Vater, when transpapillary drainage is impossible and/or dangerous. No postoperative complications were noted; the 3 patients were discharged in good condition 2 or 3 days after the drains were removed.

9670 RESULTS OF OPERATIONS ON THE BILE DUCTS. (Ger.) Herzog, K. H. (U. Clin. Rostock, Germany), E. Smolinski and S. Kiene. Bruns. Beitr. Klin. Chir. 214(3):338-348, 1967.

A report is made on 604 operations on the biliary system, 493 in women (81.6%) having an av. age of 45.2 yr., and 111 in men (18.2%), av. age 52.5 yr. The medical records of 182 patients have been retained for more than 5 yr. More than half the patients had suffered biliary symptoms for over 3 yr. A total of 344 had undergone 1-4 different medical treatments in hospital and 181 ambulatory patients had been under physicians' care for more than 3 yr. Typical stone colic in simple and aggravated form was the chief complaint recorded; 428 patients had suffered at least intermittent colic-like attacks; 106 of these cases also had jaundice; and in 50 cases, pancreatitis. The patients had undergone various other diseases and operations prior to the one on the biliary system. Intraoperatively, stones were found 559 times in the gallbladder and 103 times in the main bile ducts. Inflammation of the gallbladder occurred in 310 and of the bile ducts in 18. Macroscopic evidence of pancreatitis appeared in 14; 4 cases of hepatitis and 1 of hepatic cirrhosis were verified; there were 16 cases of papillary stenosis; 13 tumors were encountered, 5 in the gallbladder and 4 i the ducts; 1 was on the papilla, 1 on the head of the pancreas, and 1 on the liver. The oper tive procedures resulted in 271 simple chole cystectomies, 163 cholecystectomies with choledochotomy and exploration of the main ducts. T-drain was placed in the common bile duct 159 times; the primary duct had to be closed by su 4 times. A number of other special technics h to be employed, as an example, in 13 patients biliodigestive anastomoses were constructed. postoperative period was passed without compli tions in 458 cases; 60 suffered general compli tions, 68 local complications and 18 both. General complications were pneumonia, pleuriti thromboemboli and the like. Local complicatio involved disturbances in wound healing. The primary mortality was 3.14%, due in part to bi digestive anastomoses some of which required a second surgical intervention, increasing the r Sometime later a questionnaire was sent to all patients; 425 answered; 214 were without any troublesome symptoms; 279 could eat all foods.

9671 MECHANISM OF JAUNDICE DUE TO BILIARY OBSTRUCTION AFTER 4 DAYS. (Fr.) Mallet-Guy, P. (Edouard-Herriot Hosp., Lyon, France), J. Michoulier, L. F. Kesner and M. Nugeyre. Lyon Chir. 63(1):17-20, 1967.

Chicago Blue was inj. in the common bile duct of dogs under pressure of 30-cm H_2O. In the f hr. following common bile duct obstruction, it was noted that biliary pressure and bilirubin the thoracic duct rose rapidly, while serum bilirubin rose slowly; following removal of th obstruction, lymph and serum bilirubin were re progressively. Thus, it appears that the lymp compartment serves as an intermediary between the biliary and blood systems. In another ser of research, biliary-lymphatic passage was stu 4-8 days after the common bile duct obstructio utilizing again the Chicago Blue; there was no reflux of dye from the biliary into the lympha system when the common bile duct was subjected pressures of 40-cm H_2O, and only in 25% of cas there was reflux into the lymphatic system und a pressure of 60-cm H_2O. Thus, it appears tha the permeability of the biliary-lymphatic syst is the essential mechanism of jaundice, but th mechanism is inoperable when pressures with th common bile duct are within normal limits, e.g 30-40 cm H_2O.

9672 BLOOD-VOLUME AND HYPOTENSION IN OBSTRUCTIVE JAUNDICE. (E.) Cattell, W. R. (St. Bartholomew's Hosp., London) and M. Birnstingl. Brit. J. Surg. 54(4):272-278, 196

Blood vol. studies carried out on 25 patients and on 17 dogs with obstructive jaundice are described here to find what evidence there is blood-vol. deficits such as have been describe in this condition. The effect of hemorrhage o mean systemic pressure in jaundiced, compared

nonjaundiced animals, was studied on 20 dogs.
umans, the measured blood-vol. exceeded the
icted blood-vol. in 11 of the 14 patients. In
als no significant difference was demonstrable
he jaundiced compared with the nonjaundiced
plasma-vol. and blood-vol. were expressed
l/kg body wt. The effect of hemorrhage on
systemic pressure varied in individual dogs,
a mean reduction occurred. It was concluded
an increased predisposition could be demon-
ted in animals with obstructive jaundice after
er blood losses than 30% of total blood vol.,
h does not explain the observed high incidence
ypotension in surgery patients with obstructive
dice who have lost little blood, so that no
d rationale exists for pre-operative blood
sfusions in such cases.

ACTION OF VARIOUS NEW ANALGESIC DRUGS ON THE HUMAN COMMON BILE DUCT. (E.)

on, D. S. (Manchester Roy. Infirm., England)
H. B. Torrance. Gut 8(3):296-300, 1967.

sure changes in the common bile duct were
ured in postcholecystectomy patients following
n. of levorphanol, dextromoramide, dextro-
oxyphene, phenoperidine or phenazocine. Re-
s were compared with pressure rises produced
.m. admin. of morphine and pethidine. Pres-
changes were graded as marked (10-cm or more),
rate (5-10-cm or more), minimal (less than
) and no change. Both levorphanol and pheno-
dine in doses of 2 mg i.m. were comparable
10 mg i.m. of morphine. Dextropropoxyphene
n. produced no changes in biliary pressure
was considered comparable with codeine.
romoramide in doses of 5 mg i.m. was comparable
10 mg i.m. of morphine. Phenazocine was
idered stronger and safer in treating biliary
than morphine with doses of 2 mg i.m. of
former being stronger than 15 mg i.m. of
hine.

PARA-VATERIAN DIVERTICULA AND THEIR RELATIONSHIP TO BILIARY TRACT DISEASE.

.) Friedman, E. (Cent. Emek Hosp., Afula,
el). Harefuah 72(5):172-179, 1967.

08 cases of duodenal diverticula diagnosed
-ray, 53 were para-Vaterian. Av. age was
r. and number of males and females was equal.
5 undergoing X-ray examination (p.o., i.v. or
) of the biliary tract, biliary tract disease
observed in 11. Av. age of those with disease
66; of those without, 50. Of 55 who had duo-
l diverticula other than para-Vaterian, biliary
t disease was diagnosed in only 4. Of the
ith biliary tract disease, there were 5 males,
males and the duration of complaints was
yr., except only briefly in 1. The chief
laint was recurrent pain in the right upper
men. Jaundice was transitory in 2 of 3 cases
hich it occurred. In the 1 case of acute
reatitis, an apparently healthy gallbladder
removed. Of 7 patients operated on, 6 had a dilated common bile duct, and 3 of these had calculi in both the bladder and the common duct, 1 only in the bladder, and 2 had no calculi. In all but 2, the para-Vaterian diverticuli were demonstrated preoperatively, in 1 during intraoperative cholangiography and postoperatively in the other. In 2, the common bile duct entered the diverticulum at the base of its neck. The coincidence of para-Vaterian diverticula and biliary tract disease was common, being 44% of those with biliary tract disease in this study as opposed to 20% of the whole group. It is suggested that every patient above age 50 in whom a para-Vaterian diverticulum is found on upper gastrointestinal examination should have a full biliary tract examination, even if complaints seem to be due to other causes.

9675 LIVER IN CONGENITAL BILE DUCT ATRESIA: HISTOLOGICAL CHANGES IN RELATION TO AGE.

(E.) Shiraki, K. (U. Tokyo), M. Odawara, M. Higurashi and Y. Okamoto. Paediat. Univ. Tokyo (12):68-78, 1966.

Liver histological examination was made in 51 cases of congenital bile duct atresia in pediatric patients. Specimens (52) were fixed in 10% formalin, and stained with hematoxylin and eosin, periodic acid-Schiff and van Giesson-Elastica stains. Giant cells were observed in 33 of 52 specimens (63%) and in 31 of 39 (80%) obtained before 5 mo. of age. Several giant cells contained 40 nuclei, and 24 of 52 (46%) had more than 10. The max. number of nuclei decreased with increasing age, with a peak at 2-4 mo. Bile duct hyperplasia was observed in 49 (94%) and increased in parallel with age until 5 mo. when it diminished as fibrous tissue increased in the portal area. There was essentially no difference in degree of bile duct hyperplasia between correctable and non-correctable bile duct atresia. Degree of bile stasis in the portal area increased with age until 6 mo. There was no correlation between the degree of intra- and intercellular bile stasis and age. There was a significant regression between degree of fibrosis (measured planimetrically) and age, to 6 mo. of age. There was no relation between degree of fibrosis and age. Those with severe fibrosis were all above 3 mo. of age. There was no difference in degree of fibrosis between correctable and noncorrectable bile duct atresia. There was a statistically significant correlation between degree of fibrosis and thymol turbidity test and zinc sulfate turbidity test. High test levels were indicative of severe fibrosis, but normal values did not imply slight fibrosis. Neither serum bilirubin, serum total cholesterol, alkaline phosphatase, total protein nor serum albumin:globulin ratio correlated significantly with degree of fibrosis. Livers of those with correctable atresia had a slight degree of bile stasis in the portal area and a slighter tendency toward giant cell transformation. It is suggested that these age-related histological changes should be considered when making a liver biopsy diagnosis of patients with prolonged obstructive jaundice.

9676 SIGNIFICANCE OF ALLERGY IN THE PATHOGENESIS OF HEPATITIS AND CHOLECYSTOANGIOCHOLITIS. (Rus.) Podobedov, V. B. (Med. Inst., Kiev, USSR). *Vrach. Delo* (11):11-14, 1966.

A study was made of 103 patients with hepatic cirrhosis, chronic hepatitis with or without pronounced symptoms of cholecystitis and angiocholitis, cholecystitis and angiocholitis with slight symptoms of hepatitis, or liver and bile tract pathology superimposed upon allergy (drug allergy, urticaria, bronchial asthma); 60 had allergic symptoms and 40 of these were studied in detail. The Widal's-Vogan test was positive in 18 of 22 subjects tested, i.e., WBC was decreased by more than 1000, 12 had tachycardia, 1 had paroxysmal tachycardia, some had heat reaction, vertigo and urticaria, and infrequently Quincke's edema. Twelve patients with drug allergy (on antibiotics, aminopyrine, sulfanilamides, hormones, bromine, iodine) improved on desensitizing therapy. The Boyden reaction revealed the presence of antibodies in liver tissue in 22 of 24 patients studied. In 12 patients examined, the eosinophil content varied from 6-90%. A general blood study revealed more than 4% eosinophils in 16 of 40; less than 24% lymphocytes in 12 of 40 and more than 30% in 15 of 40; less than 6000 WBC were found in 25 of 40, less than 4000 in 3 of 40, and the RBC sedimentation rate was more than 12 mm/hr. in 7 of 40; globulins were increased in 40 of 40 (particularly the γ-fraction). A slight liver function disturbance was evident in 26 of 40, moderately severe disturbance in 12 of 40, and marked changes in liver function were present in 2 of 40. Desensitizing therapy yielded subjective and objective improvement.

9677 CHOLECYSTITIS TREATED WITH PYRIDINE-3-CARBOXYLIC ACID-HYDROXYMETHYLAMIDE (BILAMID). A STUDY OF 588 PATIENTS ADMITTED FOR TREATMENT OF BILIARY TRACT DISORDERS. (Dan.) Martiny, P. J. (Holstebro Cent. Hosp., Denmark) and K. Baldvinsson. *Ugeskr. Laeg.* 129(13):419-421, 1967.

A total of 558 patients were surgically treated over a 10-yr. period, 302 for cholecystitis, and 256 for cholelithiasis; of the 302 cases of cholecystitis 168 received Bilamid (pyridine-3-carboxylic acid hydroxymethylamide) therapy (2 x 3 tablets/day for 2 days then 1 x 3 tablets/day) for 40 days each; of the 256 patients with cholelithiasis, 37 received Bilamid treatment in the same dosages, but for only about 25 days. A total of 134 cases of cholecystitis and 219 of cholelithiasis did not receive Bilamid. Altogether those with cholecystitis treated with Bilamid were in the hospital 8 days fewer than those who did not receive the drug. Cholelithiasis patients with the drug spent 4 days less in hospital. It is concluded that although the number of patients was small, Bilamid seems to exert a beneficial effect. The mode of action of the compound is unknown; it does in some instances reduce fever. An investigation is underway with a larger number of patients in attempt to discover its mode o
action.

9678 THE DIFFERENTIAL AND DIAGNOSTIC SIG
NIFICANCE OF PERIDURAL BLOCKADE IN
ACUTE CHOLECYSTITIS AND CHOLECYSTOPANCREATITI
(Rus.) Nosov, G. E. (Vladivostok Med. Inst.,
USSR). *Vestn. Khir. Grekov.* 98(4):65-70, 196

Extradural (peridural) blockade, performed on

9679 MINEROLOGY OF GALLSTONES. (Ger.)
Mosebach, R. (Justus Liebig U., Gi
Germany). *Gastroenterologia (Basel)* 107(1):
1967.

Gallstones from 145 cholelithiasis cases wer
studied minerologically for composition,
structure and interrelationships, including
studies of powder and thin sections under th
polarization microscope. X-ray diffraction
studies were made of powdered gallstones.

tones were subjected to quantitative chemical
ses to determine their composition; the
cal integration in concrements required split-
polishing and grinding, dessication, soln.
ecrystallization to determine in what stages
equences the stones were formed. Cholesterol
different crystalline forms, optically dif-
tiated have appeared; 2 of these were found
single large concrement from a 60-yr.-old
nt. Analysis showed that the largest com-
ts of gallstones are lipids, cholesterol
the principal one followed by fat, bile acids,
ubin (usually a minor amount); Ca is present
ly in the form of carbonate; very little
hate was present. There are 3 types of
tones; the first is spoken of as a mulberry
spberry stone (22%); the most common type
is a concrement generally flat-sided bounded
gles and corners; these are often designated
ceted, but which the author prefers to call
edral; the third type (19%) is more or less
ical, ellipsoidal or completely irregular
tones. As a rule the mulberry or raspberry
has a relatively low wt. and a relatively
diameter and is a single concretion with
w-to-brown and even green colors. The thin
on showed a peculiar structure which the
r has seen in all raspberry stones; this
ture is formed of small spherical or ellip-
l bodies which at once form concentric shell-
ed structures and rays of crystalline chol-
ol radiating from the center. The polyhedral
when cut and polished, clearly showed that
der generation of raspberry stones had grown
a polyhydral one.

PERSISTENT, POSTOPERATIVE, ISOLATED
DILATATION OF THE PRINCIPAL BILE DUCT,
TRIBUTORY FACTOR IN SECONDARY FORMATION OF
S. (Fr.) Mallet-Guy, P. (Fac. Med.,
France) and M. Gignoux. Lyon Chir. 63(3):
31, 1967.

ilatation of the main biliary duct has been
ved as the only apparent cause of the post-
cystectomy syndrome in 25 cases; now 9
ementary observations indicate a new dimension
nsequence of such dilatation, the secondary
pitation of a lithiasis in the duct. All
were operated upon with manometric and
logic control giving an absolute proof of
ce of obstruction in the duct. Formation of
in this situation was probably caused by
stasis. It is stated that choledochoduo-
tomy is especially indicated in these aspects
mmon duct lithiasis, and even in the dilata-
alone. Clinical evidence and radiological
es seem to justify such a procedure which is
nly one giving a reduction in the diameter
e duct and preventing stasis. Re-operation
elapse of cholecystectomy attained an im-
nt percentage in the practice of 1 of the
rs reaching 27%, 133 cases of stone in the
duct in 492 operated patients.

9681 RELATIONSHIP OF CHOLECYSTOGRAPHIC VISUALIZATION OF GALLBLADDER TO INCIDENCE OF CHOLEDOCHOLITHIASIS. (E.) Woolam, G. L. (Mayo Clin., Rochester, Minn.), F. J. Freeman and J. T. Priestley. Surgery 61(5):669-671, 1967.

Although the interpretation of roentgenologic findings has been among the usual criteria for deciding the feasibility of exploratory choledochotomy any additional information indicating the likelihood of choledocholithiasis is useful. The present study determined the relative incidence of choledocholithiasis when cholecystographic findings indicated a functioning gallbladder with stones, compared with the incidence with a nonfunctioning gallbladder. The records of 500 consecutive patients who had undergone elective cholecystectomy during 1965 for chronic cholecystitis with cholithiasis were examined. Patients with jaundice, or with a history of jaundice, were excluded from the study. Cholecystography, with oral admin. of iopanoic acid (Telepaque), had been performed preoperatively at least once on all patients. Common duct stones were found in 5.4% (27 patients). Among the 361 patients with gallbladders which had been visualized by preoperative oral cholecystography, the incidence of choledocholithiasis was 3% (12 patients). Among the 139 patients with nonvisualization of the gallbladder, common bile duct stones were found in 11% (15 patients). The fact that choledocholithiasis is more commonly present in patients with nonopacifying gallbladders should be helpful in scheduling surgical exploration of the common ducts.

9682 CLASSIFICATION OF PARIETAL DYSPLASIAS OF THE GALLBLADDER. (It.) Cataliotti, F. (U. Palermo, Italy), L. Li Castri Patti and U. Parodi Giusino. Minerva Chir. 22(6):344-357, 1967.

In a series of 503 cholecystographic examinations, five patients (4 women and 1 man; age 30-60 yr.) with parietal dysplasia of the gallbladder without gallstones were observed. These patients represent 1.4% of 346 patients of the same series subjected to cholecystectomy. Histologically, all patients showed mucosal hyperplasia with papilla-like structures and elements of adenomyomatosis. Sex distribution (female:male ratio 4:1) was similar to that reported by other authors. All patients were subjected to cholecystectomy and disappearance of symptoms followed; follow-up was 2 yr. in 3 patients and 1 yr. in the other 2. In a statistical study of the incidence of dysplastic lesions of the gallbladder in patients with gallstones, only 2 cases (1 with adenomyomatosis of the fundus and 1 with intramural diverticulosis) were observed among 100 gallbladders examined. The authors recommend that the term "cholecystosis" be applied only to dysplastic parietal lesions of the gallbladder. The correct interpretation of radiological and cholangiographic data in the differential diagnosis of parietal dysplasias, as well as their medical and surgical treatment, are discussed.

9683 CARCINOMA OF THE GALLBLADDER AND THE BILE DUCTS.

(Ger.) Burckhart, T. (City Hosp., Russelsheim, Germany) and D. Loew. Bruns Beitr. Klin. Chir. 214(3):314-337, 1967.

In 2204 operations on the bile ducts, 63 cases (2.8%) of carcinoma of the gallbladder and 45 cases (2.0%) of carcinoma of the bile ducts were observed; women (59) predominated in gallbladder carcinoma, whereas the number of women with carcinoma of the bile duct was 22 and the number of men 23. The majority of patients were 55-65 yr. old with an av. age of 62 yr. Of the 63 gallbladder carcinoma cases, 46 were histologically verified, as were 36 of the bile duct carcinoma cases; 94.4% gallbladder cases were adenocarcinoma as were 80.4% of the bile duct carcinomas, anaplastic carcinoma occurred in 2.8% of the gallbladder carcinoma and 13.0% of the bile duct carcinomas. Squamous epithelial carcinoma made up the remainder. The primary site of gallbladder carcinoma is not always discernable; mostly it arises in the fundus, in the neck of the bladder or in the wall adjacent to the liver; there are 2 forms, a diffuse infiltrating type which spreads faster, and a knot-like, compact and circumscribed form. The gallbladder carcinoma of the fundus shows the greatest metastatic distribution (colon, small intestine and forward abdominal wall, lymphatics, vascular structures and nervous system). The bile duct carcinoma was located about the hepatic bifurcation of the duct, the mouth of the gallbladder and in the duct below the gallbladder; the forms were villous, nodular or diffuse. The metastases can occur in the same regions as those of gallbladder carcinoma; growth of bile duct carcinoma is slower. Gallbladder carcinoma showed metastases in 85% of cases; bile duct carcinoma had metastasized in 70%. Symptomatology and diagnosis presented difficulties: Right-sided upper abdominal diffuse pain occurred in 58.7% of gallbladder cases and 42.2% of bile duct cases. Jaundice was present in 57.1% of gallbladder carcinoma, and 91.3% of bile duct. Colic occurred in 41.3% of the former, and 4.3% of the latter. Loss of appetite and body wt., a feeling of illness and emesis were other indications. Increased sedimentation rate was useful; serum bilirubin (in the region of 20 mg%) is indicative. Liver function tests were useless. X-ray examination proved helpful in 7 of 27 cases. Etiology and genesis of these cancers is not clear. The prognosis in both types of carcinoma is not good because of rapid early growth, the frequent delay in correct diagnosis and the tendencies to metastasis. The longest survival after operation for bile duct carcinoma has been 1 yr. One case of gallbladder carcinoma has survived 3.5 yr., another 5.5 yr.; all others survived less than 1 yr.

9684 CHOLECYSTOKININ IN X-RAY EXAMINATIONS.

(Sw.) Backlund, V. (City Hosp., Kiruna, Sweden). Lakartidningen 64(24):2473-2476, 1967.

The author instituted the use of cholecystoki
in place of egg yolk or a fat meal to stimula
contraction of the gallbladder and noted 2 o
actions of the hormone in the course of trea
400 patients having well-filled gallbladders
no concretions. About 50% of the cases retu
to normal gallbladder function; the others d
veloped some degree of pathology such as poo
filling with contrast material, impaired ton
no filling with contrast material, or the fo
of concretions; these conditions represented
forerunner of possibly severe pathologies wh
could be prevented by return to normal funct
through proper treatment. The rate of passa
of Ba contrast material in the small intesti
was much increased without any discomfort to
patient; however, this effect was so variabl
no practical use could be made of it. The
author's technic consists of emptying the st
of contrast material in the recommended mann
having the patient lie on his right side for
min. following X-ray examination of the stom
(providing that pyloric stenosis is not pres
The cholecystokinin (35 Ivy dog U in 5-10 ml
iological saline/adult, 20 Ivy dog U/child,
yr. old) is then inj. i.v. The contrast med
is carried to the cecum within 5-15 min. as
pared to the usual time of 2-8 hr. in normal
dividuals. These 2 effects are interrelated
was demonstrated in 186 patients (70 men and
women), undergoing X-ray examination of the
stomach. After lying on the right side for
min. each patient was inj. with cholecystoki
X-ray films were taken of the abdomen 5, 10,
and 20 min. after inj. and then, when necess
hourly. The passage of the small intestine
curred within 20 min. in 139 cases (58 men a
81 women); 47 had passage times of 1 hr. (1
or more. These 47 showed 1 or more patholog
conditions of the biliary tract, including s
or no filling of the bladder, stones, and/or
muscular contraction. The underlying factor
the production of these effects are unknown.
Within limits, the effect on passage of cont
material was proportional to the amount of h
mone inj.

9685 EFFECTS OF SELECTIVE VAGOTOMY ON T MORPHOLOGY AND FUNCTION OF THE GALLBLADDER AND PRINCIPAL BILIARY TRACT.

(I
Misiti, G. (S. Salvatore Hosp., Rome), B. Sb
and S. Broglia. Gazz. Int. Med. Chir. 72(8)
662, 1967.

Cholecystocholangiographic examinations were
ducted before and 2-6 mo. after surgery in 8
patients with gastroduodenal ulcer in order
ascertain the effects of selective vagotomy
the gallbladder and principal bile ducts. S
tive anterior and truncular posterior vagoto
performed in 21 patients (Group 1); gastroen
ostomy was associated in 11 patients and pyl
plasty (9 Heineke-Mikulicz; 1 Finney) in 10.
Selective anterior and posterior vagotomy wa
performed in 59 other patients (Group 2);

roenterostomy was associated in 18 and py-
plasty (39 Heineke-Mikulicz; 2 Finney) in 41.
rged gallbladders were observed in 71.6% of
ents of Group 1 and in 45.7% of Group 2. The
est incidence of enlarged gallbladder (42.9%)
observed in patients of Group 1 subjected to
roenterostomy. The high incidence of enlarged
bladders following selective anterior and
erior vagotomy is probably due to accidental
ioning of, or operative trauma to, the hepatic
of the vagus. The gallbladder showed no
ge after surgery in 23.6% of patients of Group
d 49.1% of those of Group 2. Enlargement of
principal bile ducts after surgery was seen
3.6% of patients of Group 1 and 6.6% of those
roup 2; no change in the principal bile ducts
r surgery was observed in 71.5% of patients
roup 1 and 88.3% of those of Group 2, but
difference is not statistically significant.
ite the high percentage of gallbladder and
duct alterations revealed radiologically,
esponding clinical symptoms were not observed
hese patients.

SELECTIVE VAGOTOMY OF THE LIVER AS
PREVENTION AND CURE OF DISEASES FOLLOWING
RPATION OF THE GALLBLADDER. (Ger.) Iliescu,
lexandru-Sahia Hosp., Bucharest, Rumania).
Chir. 92(19):661-665, 1967.

ncidence of complications, such as chronic
reatitis, liver pediculitis, chronic Odditis,
ic hepatitis and spasm of the sphincter of
following surgical removal of the gallbladder
lved about 33% of the patients undergoing
operation. In 2 yr. more than 40 chole-
ctomies with selective vagotomy of the liver
been performed. Postoperative courses have
benign and symptom-free: Pain, subicterus
angiocholitis and other sequellae have literally
ppeared. There has been only 1 exception,
to a stone in the bile duct removed by chole-
otomy. The method is effective in operations
associated disorders of the biliary tract.
selective vagotomy of the liver is simply
ied out: the motor plexus to the biliary
em lies in the region of the lesser omentum
s easily found; the cranial portion of the
er omentum, associated with the left lobe of
liver, bears the nerve fibers (1) of the left
s. In the caudal region of the lesser omentum
the recurrent rami (2) of the gastrohepatic
e and a large portion of the celiac rami (3)
ront of the gastroduodenal artery and above
pancreas. The nerve bundle (4) accompanying
blood vessel from the pylorus to the upper
of the duodenum and the ventral plexus (5)
ciated with the gastroduodenal artery are
involved. All the above structures (1-5)
cut. Some fibers from the right vagus through
celiac ramus are still intact; they apparently
ot innervate the biliary tract with motor
rs. This selective vagotomy does not affect
ric function.

9692 BILIOCOLIC FISTULAS. 11 CASES. (Fr.) Moreaux, J., J. P. Clot and J. Hepp. Arch. Franc. Mal. Appar. Dig. 56(6):515-533, 1967.

9693 AIDS IN THE DIAGNOSIS OF TRAUMATIC HEMOBILIA. (E.) Hermann, R. E. (Cleveland Clin. Found., Ohio) and S. O. Hoerr. Surg. Gynec. Obstet. 125(1):55-58, 1967.

9694 NORMAL LUMINAL SIZE OF CHOLEDOCHODUODENAL JUNCTION AS DETERMINED BY PROBE AT CHOLEDOCHOSTOMY. (E.) Braasch, J. W. (Lahey Clin. Found., Boston, Mass.) and J. C. McCann, Jr. Surgery 62(2):258-259, 1967.

9695 BILOCULATIONS OF THE GALLBLADDER. CLINICAL AND THERAPEUTIC STUDY. (Fr.) Juvara, I. (Cantacuzino Hosp., Bucharest), D. Radulescu and A. Priscu. Arch. Franc. Mal. Appar. Dig. 56(6):535-548, 1967.

9696 EFFECTS OF PARTIAL AND COMPLETE BILIARY TRACT OBSTRUCTION. (E.) Williams, R. D. (U. Texas Med. Branch, Galveston). J. Okla. Med. Ass. 60(7):390-394, 1967.

9697 OBSERVATIONS ON RADIOLOGIC DIFFERENTIAL DIAGNOSIS OF SO-CALLED "HOOK-SHAPED" DEFORMATIONS OF THE GALLBLADDER. (It.) Cosmacini, G. (Maggiore Hosp., Milan, Italy). Ann. Radiol. Diagn. (Bologna) 40(4):331-338, 1967.

9698 IS IODINE INTOXICATION AFTER PEROPERATIVE CHOLANGIOGRAPHY POSSIBLE? (Fr.) Sciacca, M. F. (Riuniti Hosp., Rome). Arch. Franc. Mal. Appar. Dig. 56(6):557-562, 1967.

9699 CHOLANGIOCHOLECYSTOGRAPHY BY MEANS OF INFUSION OF CONTRAST MEDIUM IN HIGH DOSAGE. (It.) Romani, S. (U. Padua, Italy) and A. Chiesa. Quad. Radiol. 32(2):281-304, 1967.

9700 FUNCTIONAL BEHAVIOR OF THE EXTRAHEPATIC BILIARY TRACT IN THYROID INFECTIONS. RADIOLOGIC STUDY. (It.) Paolini, F. A. (U. Pavia, Italy), P. Garbagna, M. Gazzaniga, C. Vecchio and F. Casolo. Quad. Radiol. 32(2):189-203, 1967.

9701 DIAGNOSIS OF BILE STONE ILEUS AND ITS RESULTANT BILIO-INTESTINAL FISTULA. (Ger.) Geisthövel, W. (St. Bernwards Hosp., Hildesheim, Germany). Landarzt 43(19):918-922, 1967.

9702 CHOLELITHIASIS AND CHOLECYSTITIS IN CHILDHOOD. (E.) Wingert, W. A. (U. Southern California Sch. Med., Los Angeles) and V. G. Mikity. Calif. Med. 107(1):26-32, 1967.

9703 CHOLECYSTITIS AND THE HYPERPLASTIC CHOLECYSTOSES: A CLINICAL, RADIOLOGIC, AND PATHOLOGY STUDY. (E.) Lubera, R. J. (Harper Hosp., Detroit, Mich.), A. R. W. Climie and G. E. Kling. Amer. J. Dig. Dis. 12(7):696-704, 1967.

9704 HEMORRHAGE FROM THE GALLBLADDER. A REPORT OF THREE CASES. (E.) Polse, S. (U. California Sch. Med., San Francisco), R. J. Stoney and J. N. Baldwin. Calif. Med. 107(1): 51-53, 1967.

9705 BENIGN TUMORS OF THE EXTRAHEPATIC BILIARY DUCTS. (It.) Valentino, A. (Maggiore Hosp., Bergamo, Italy) and C. Bonzanini. Minerva Chir. 22(10):637-642, 1967.

9706 PRIMARY CARCINOMA OF THE MAIN BILE DUCT. (Pol.) Zakrys, M. (2nd Surg. Clin., Lublin, Poland). Ann. Univ. Curie Sklodowska [Med.] 20:265-272, 1966.

9707 DISRUPTION OF THE SLEEPING-WAKING REGULATION DURING CHOLECYSTITIS. REPORT OF PERSONAL OBSERVATIONS. (Ger.) Bilz, R. (Beuthenerstrasse 9, Munich, Germany). Med. Welt 18(29):1699-1704, 1967.

9708 USE OF OXYGEN AND MULTIPLE VITAMINS
THE COMPLEX TREATMENT OF PATIENTS WI
CHRONIC CHOLECYSTOANGIOCHOLITIS. (Rus.) Shch
penko, I. M. (Kiev Med. Inst., USSR). Vrach.
Delo (6):21-24, 1967.

9709 ULCER AND GASTRITIS IN CHOLECYSTITIS
(Ger.) Koch, G. (U. Hamburg-Eppendo
Germany) and R. Petzoldt. Bruns Beitr. Klin.
Chir. 214(4):459-464, 1967.

9710 SEPTIC CHOLANGITIS AND CHOLECYSTITIS
DIAGNOSTIC AND MANAGEMENT PROBLEMS.
(E.) Fratkin, L. B. (750 W. Broadway, Vancouv
B.C., Canada). Pacif. Med. Surg. 75(4):230-23
1967.

9711 FUNCTIONAL STATE OF THE GALLBLADDER
PATIENTS WITH TYPHOID AND DYSENTERY.
(Rus.) Lindenbraten, L. D. (Sechenov 1st Mosc
Med. Inst.) and G. V. Klyvak. Sovet. Med.
30(6):48-51, 1967.

9712 HYPERPLASTIC CHOLECYSTOSIS--SEGMENTA
ADENOMYOMATOSIS TYPE. REPORT OF TWO
CASES. (E.) Jelaso, D. (Camp Zama Army Hosp.
San Francisco, Calif.), C.O. Burdick and R. K.
Brown. Arch. Surg. (Chicago) 95(1):70-73, 196

9713 PAROXYSMAL TACHYCARDIA IN BILIARY TRACT DISEASES. (Ger.) Marburger,
(City Hosp., Karlsruhe, Germany). Med. Welt 18(30):1708-1710, 1967.

9714 LATE FUNCTIONAL RESULTS OF CHOLEDOCH
DUODENOSTOMY OF "RELATIVE INDICATION
I. ANALYSIS OF A NEW SERIES OF 159 CASES (195
1964). (Fr.) Mallet-Guy, P. (Fac. Med., Lyon
France) and P. Jouvinroux. Lyon Chir. 63(4): 543-559, 1967.

9715 LATE FUNCTIONAL RESULTS OF CHOLEDOCH
DUODENOSTOMY OF "RELATIVE INDICATION
II. DANGER TO THE TEETH. (Fr.) Mallet-Guy,
(Fac. Med., Lyon, France) and J. Michoulier. Lyon Chir. 63(4):560-565, 1967.

9716 SURGICAL ANATOMY OF THE HUMAN EXTRA-
HEPATIC BILE DUCT SYSTEM AS SEEN AT
OPERATION AND BY ROENTGENOGRAPHIC EXAMINATION.
(E.) Hayes, M. A. (Yale U. Sch. Med., New Hav
Conn.). Pacif. Med. Surg. 75(4):205-216, 1967

9717 SURGERY OF THE BILIARY TRACT. (E.)(Rev.) Ferris, D. O. and W. A. Sterling. Surg. Clin. N. Amer. 47(4):861-875, 1967.

LIVER, injury, toxic agents (Contd.):
      CCl_4: 9569*,9571*,9574*,9592,9650*
      ethionine: 8828*
  metabolism: 8827*,8832*,8835,8841,8850,8861, 8863,8870,9083*,9476*,9508,9524
    carbohydrate: 8862,8889,8891,8892,8893, 9134,9473*,9567*,9572*,9573*,9587,9654
    cholesterol and steroid: 8824*,8839,8842, 8844,8886,8892,9287,9464*,9466*,9587,96
    copper: 9432*
    drug: 8743,8824*,8830*,8838,8845,8847, 8848,8851,8853,8854,8857,8859,8860, 8868,8883,8887,8894,9448*,9536,9583,958
    iron: 8831*,8885,9279,9496*
    lipid: 8842,8876,8877,9447*,9448*,9464*, 9576*,9581*
    nucleic acid: 8871,8872,8873,8874,8875, 8878,8880,8896
    protein: 8836,8837,8874,8882,8889,9289, 9499*,9507,9586
  morphology: 8709*,8710*,8828*,8832*,8838, 8840,8869,8879,8882,8896,9446*,9468*,9481* 9487*,9491*,9547,9569*,9585,9642*
  neoplasms: 9543
    benign: 9503
    malignant: 9436*,9437*,9450*,9454*,9456*, 9462*,9469*,9489*,9490*,9501,9502,9504, 9506,9507,9668
  nervous control: 8709*,9566*,9596*
  perforation: 9489*
  perfusion: 8825*,8833*,8864,8865,8873,8894, 9444*,9445*,9446*,9455*,9476*,9479*,9482*, 9524,9572*
  plasma proteins: 8865,9143*,9450*,9480*,9570 9579,9661,9676*
  regeneration: 8826*,8831*,8878,8880,8881, 8882,8883,8884,9435*,9481*,9486*,9488*, 9489*,9490*,9497*,9501,9574*
  reticuloendothelial system: 8886,8888,9447*, 9582
  secretion: 8857
  surgery: 9517,9534
  toxic effects
    chemical: 9567*,9588
  transplantation: 8826*,9439*,9440*,9441*, 9442*,9443*,9525
  trauma: 9531,9560
  vitamin B_{12} (see also Absorption; Malabsorption; Vitamins): 8871
LYMPH: 8712,8965,9487*,9651*

MALABSORPTION (see also Intestine, Small; Steatorrhea): 9273,9532
  children: 9283
  diagnosis: 9277
    biopsy: 9257*,9276
    tolerance tests: 9257*,9259*,9267*
    D-Xylose: 9274,9276,9381*
  pathophysiology
    disaccharidase deficiency: 9257*,9267*,928
    intolerance, sugar or milk: 9256*,9257*, 9259*,9261*,9265*,9266*,9267*,9268*, 9280,9281,9282,9283
    microorganisms: 9270*
    steatorrhea (see also Steatorrhea)
    vitamin deficiencies: 9118,9276

SORPTION (Contd.)
- imary
  - celiac disease: 9143*,9258*,9261*,9262*, 9266*,9268*,9272
  - sprue: 9262*
- condary
  - gastric surgery: 9278,9285,9286
  - intestinal resection: 9278
- eatment
  - antibiotics: 9262*,9270*
  - dietary: 9257*,9262*
  - folic acid: 9262*
  - vitamin B_{12}: 9262*

L'S DIVERTICULUM: 9161,9162

OLON: 9339,9344,9365*

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis and Metabolic Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication of GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available, free to qualified interested investigators and practitioners, citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology had accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis and Metabolic Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published. Requests from qualified individuals to receive free copies of this publication, and address changes and other communications from these individuals should be addressed to:

8 IN VIVO OBSERVATIONS ON MICROCIRCULATION
IN THE SPLANCHNIC REGION FOLLOWING
NEPHRINE STIMULATION. (It.) Bellodi, G. (U.
ma, Italy) and P. Sartoni. Riv. Gastroent.
3):156-168, 1967.

e Wistar rats (wt. 250 g) were subjected to
arotomy and a cannula inserted into the ascend-
vena cava. At this point, circulation at the
el of the hepatic sinusoids and pancreatic
illaries was directly observed by means of a
ocular microscope equipped with a special il-
inating lens and a Zeiss Ultropak objective
s with a magnifying power of 110, 180, and 230
es. Observations were repeated after inj. into
cannula of 0.1-0.2 ml of a 0.2% soln. of
nephrine. At the external surface of the
er, under normal conditions, the blood vessels
ich correspond to the subcapsular sinusoids)
e numerous and of various diameters, arranged
a linear, parallel, pattern; smaller vessels
ted to form larger ones, which then continued
p into the parenchyma; blood seemed to flow
m the deeper portion of the organ, where the
usoids were tortuous and formed many anasto-
es; RBC moved at high speed and freely within
large vessels. After the inj. of epinephrine,
eaction phases were observed: in Stage 1,
sinusoid walls collapsed, blood flow was
ter, and few RBC were seen within the blood
sels; in Stage 2, progressive increase in
ber and massing of RBC was observed along with
arked decrease in blood flow, frequently caus-
death in the animals. In surviving animals,
culation returned to normal within 10-20 sec.
animals treated with a second dose of epin-
rine, the reduced RBC flow stage was always
dent, although the dilatation stage was less
ked. Under normal conditions, the blood ves-
s of the pancreas were directed from the peri-
ral portion of the gland towards the center;
y were usually of very small diameter and
tuous; blood flow was always lively, with
stant and continuous, if not very rapid, RBC
w. After epinephrine, marked vasoconstriction
observed in pancreatic blood vessels; capil-
ies were emptied in a short time, with occas-
al RBC passage; larger vessels also decreased
caliber but maintained a rapid blood flow.
effect was greatest after 3 min., and if the
mal survived, capillary circulation returned
normal.

9 ALBUMIN SURVIVAL IN PATIENTS WITH
MASSIVE SMALL-BOWEL RESECTION. (E.)
awer, S. J. (Boston City Hosp., Mass.), T.
skovic, R. Goldsmith, S. A. Broitman and N.
check. Amer. J. Dig. Dis. 12(8):753-760, 1967.

effect of removal of major portions of the
kimal and distal small intestine on albumin
radation was studied in 3 patients, 2-12 yr.
er resection. Most of the jejunum was resected
3 patients, and in 1 patient most of the ileum
was also resected. The half-life ($T_{\frac{1}{2}}$) of inj. ^{131}I-albumin in 4 controls was 8.7 days, with a range of 7.2-10.4 days. In an 18-yr.-old boy, who had 95% of the small intestine resected after a midgut volvulus, the half-life of inj. ^{131}I-albumin was 19.8 days, and in the second, a 22-yr.-old male who had 50% of the small intestine and right colon resected after an infarcted hiatus hernia, the $T_{\frac{1}{2}}$ was 17 days. The half-life was equally prolonged in both patients despite a low (2.2 g%) serum albumin in the first, and a low-normal (3.6 g%) serum albumin value in the second patient. The $T_{\frac{1}{2}}$ of albumin was normal in the third patient, who had recurrent gastric ulcers, atrophic gastritis and gastric mucosal bleeding; this 51-yr.-old female had 85% of the small intestine resected as a result of trauma to the superior mesenteric blood vessels during surgery for removal of cancer of the colon. A $^{51}CrCl_3$ study showed slightly abnormal values in this patient, which suggested excess gastrointestinal protein loss, and this may have compensated for a prolonged albumin half-life. These studies emphasize the greater importance of the jejunum as compared to the ileum in albumin catabolism, since prolongation of ^{131}I-albumin half-life was related to resection of the jejunum and not the ileum.

9720 REACTION OF THE NEWBORN ANIMAL TO DRUGS. PRELIMINARY COMMUNICATION. (I) COMPARATIVE EFFECTS OF VARIOUS BIOLOGICAL MEDIATORS ON ISOLATED PORTIONS OF THE GASTROINTESTINAL TRACT. (It.) Cugurra, F. (U. Trieste, Italy) and A. Vaccari. Minerva Pediat. 19(15):731-737, 1967.

The effects of several autonomic drugs on various portions of the gastrointestinal tract (gastric fundus, jejunum, ileum) were studied in 138 newborn Wistar albino rats and 33 newborn guinea pigs (S.M. strain), and results compared to those observed in adult rats (11-12 mo. old) and guinea pigs (4 mo. old). The following drugs were used: serotonin creatinine sulfate; histamine- 2 HCl; furfuryltrimethylammonium iodide; nicotine tartrate; L-norepinephrine HCl; (-)isopropylnorepinephrine ("Isoprenalin"); bradykinin ("BRS-640"); and angiotensin ("Hypertensin"). All drugs were dissolved in Tyrode soln. at room temperature immediately before use; ascorbic acid (10 µg/ml) was added to the L-norepinephrine and (-)isopropylnorepinephrine soln. and atropine sulfate (10^{-7} g/ml) to the bradykinin soln. before use. Cumulative dose-response curves were obtained according to the Van Rossum technic. No significant differences were observed in the response of newborn or adult animals to histamine or bradykinin as regards the guinea pig ileum, to nicotine as regards the guinea pig jejunum, or to furfuryltrimethylammonium iodide as regards the rat jejunum. The newborn guinea pig ileum was less sensitive to angiotensin. The newborn rat fundus showed a marked decrease in sensitivity

(-235 times) to serotonin as compared to adults; however, values returned to normal by day 29. The newborn rat fundus also showed a marked decrease in response to L-norepinephrine (-230 times) as compared to adults; however, receptor affinity (pD_2) gradually increased to max. values by day 6, then decreased and reached normal values by day 29. The newborn rat fundus showed a symmetrical but opposite affinity for L- and (-)isopropylnorepinephrine; a progressive increase in sensitivity was noted towards the former as compared to progressive decrease towards the latter. No increase in sensitivity on the part of the various gastrointestinal segments of the newborn animals studied was observed towards any of the agents.

9721 PATHOLOGY OF AMINO ACID EXCESS. VII. PHENYLALANINE AND TYROSINE. (E.)

Klavins, J. V. (Brooklyn-Cumberland Med. Ctr., N. Y.). Arch. Path. (Chicago) 84(3):238-250, 1967.

A 2-part study was performed on male Sprague-Dawley albino rats. In Part 1, animals were divided into 8 groups and fed a basal diet with or without supplements of DL-phenylalanine and DL-tyrosine, the excess amino acids being added in 0.25 or 0.50 molal amounts. In Part 2, animals were divided into 5 groups and fed a basal diet, with DL-phenylalanine and DL-tyrosine added in 1.25 molal amounts. Duration of the diet was 4 wk. In Part 1, no significant differences in the various experimental groups and controls were found for food consumption, animal wt., blood urea nitrogen, hemoglobin, hematocrit, WBC, reticulocyte count and differential count of WBC. However, when the amino acids were added in 1.25 molal quantities in Part 2, there was marked damage to the pancreas, slight liver damage, deposition of Fe in the liver, hyperkeratosis of the skin, inhibition of spermatogenesis at the spermatid level and inhibition of body wt. when the animals received excessive amounts of DL-phenylalanine; such changes were not observed with excess DL-tyrosine. When both phenylalanine and tyrosine were admin. simultaneously, there was increased mortality of animals, and in the surviving animals, the changes were similar to those seen with excess phenylalanine.

9722 IN VIVO DIALYSIS OF FAECES AS A METHOD OF STOOL ANALYSIS. II. THE INFLUENCE OF DIET. (E.)

Metcalfe-Gibson, A. (Roy. Postgrad. Med. Sch., London), T. S. Ing, J. J. Kuiper, P. Richards, E. E. Ward and O. M. Wrong. Clin. Sci. 33(1):89-100, 1967.

The technic of in vivo dialysis of feces was used to discover the source of ionic constituents which are present in the normal stool. Healthy adult subjects (6 men, 1 women; 26-40 yr. old) were studied while taking various electrolyte supplements p.o., or while on diets from which the possible precursors of fecal electrolytes were omitted. The latter regimen included an electrolyte-free diet, a methylcellulose diet
and a low protein diet. Conc. of Na, K and
in fecal dialysate were little influenced by
amount of these ions in the diet. The conc.
Mg and Ca in fecal dialysate were markedly i
creased by supplements containing these ions
fell to low values during an electrolyte-fre
The conc. of phosphate and sulfate were also
creased by dietary supplements; however, pho
conc. did not decrease and sulfate conc. wer
elevated during the electrolyte-free diet.
conc. of ammonium ion and total CO_2 and the
of fecal dialysate were uninfluenced by diet
supplements of ammonium chloride and sodium
carbonate. Total CO_2 content and pH were in
creased by dietary supplements of calcium ca
and magnesium chloride; ammonium ion, total
gen and osmolality were reduced in subjects
a diet low in protein. The organic anion in
dialysate was reduced to a fourth by a diet
sisting of pure methylcellulose only. It is
concluded that Na, K and Cl are of endogenou
origin, derived from alimentary secretions,
that Mg and Ca are normally derived from the

significant shifts in the periodic motor fu
of the stomach were phasic in character. P
gastric contractions were absent in most of
dogs, with both collateral and reduced bloo
circulation, 1.0-1.5 mo. after surgery; aft
1.5-2.0 mo., periodic gastric motor activit
restored, but the amplitude of single contr
was 1.5 times greater than the basic. A co
normalization was not found even after 12-1
In an acute experiment (3 dogs), ligation
of the large gastric arteries resulted in
crease in the pressure in the left gastro-e
artery; the first order waves markedly decr
while total blood pressure in the carotid
remained almost unchanged. Subsequent liga
of similar gastric veins resulted in an in
of blood pressure to the initial level in
gastro-epiploic artery, and the amplitude
pulse fluctuation markedly increased. In
experiments, exclusion of large gastric ve
caused their pronounced dilatation, the ar
became twisted, and anastomoses developed
site of the ligature; the surrounding vess
were formed from different sources. In co
tion with functional disturbances during l
of gastric vessels, morphological shifts i
intramural nervous system were found. All
an increase in the amount of changed nerve
in Auerbach's and Meissner's plexus; these

i a reactive (Kugel phenomenon; increased argyro-
ilia, hyperchromatosis, increase in amount of
ocesses) and pathological (vacuolization of
iroplasm, disintegration of neurofibrillar ap-
ratus, nuclear pyknosis, total chromatolysis)
iracter, and showed unique topography in dif-
rent dogs. RNA content in nucleoli and neuro-
asm was changed in all animals, while nerve cell
clei showed no changes in the DNA content.

:4 STOOL PATTERNS OF HEALTHY ADULT MALES.
(E.) Rendtorff, R. C. (U. Tennessee
1. Med., Memphis) and M. Kashgarian. Dis.
on Rectum 10(3):222-228, 1967.

otal of 8267 stools were collected from 115
e subjects (prison inmates) for 6 mo., and the
tistical variables of wt. and consistency of
ols, hr. of interval between stools, daily
quency and time of day of defecation were
lyzed. Ages of the subjects ranged between
and 57 yr.; 74 (64%) were 20-29 yr. old; 33
%) were 30-39 yr. old; 6 (5%) were 40-49 yr.
; and 2 (2%) were 50-59 yr. old. The av.
ber of stools was 72 per individual, ranging
m 33-189. The period of observation av. 73
s, ranging from 39-89. The av. wt. of stools
115 individuals was 123.6 g; the median was
.7 g. In all, 46% of the stools were of a
m consistency, 36% were semiformed, 15% were
t to mushy, and 3% were loose, watery or diar-
ic. The av. interval between stools was 27.6
, indicative of a 1-day cycle; av. less than
s (i.e., 1 stool every 2 days) were a common
urrence. The av. modal time of day of evacua-
n indicated that, generally, stools were post-
ndial; preprandial evacuation occurred in
e cases. Analysis of consistency in relation
wt. of stools confirmed the general assumption
t as the passage of the stool is delayed,
er is absorbed and stools become lighter and
ner. The subjects showed distinctive individual
terns during their period of observation. Ex-
es of variability within individuals and be-
en individuals were found.

EVOKED POTENTIALS IN POSTERIOR VENTRO-
LATERAL THALAMIC NUCLEUS IN RESPONSE TO
ULATION OF MESENTERIC NERVES AND GASTRO-
STINAL RECEPTORS. (Rus.) Musiashchikova,
. (Pavlov Inst. Physiol., Leningrad, USSR).
ol. Zh. SSSR Sechenov 53(5):496-505, 1967.

ats anesthetized by chloralose (70-80 mg/kg
) and immobilized by gallamine triethiodide
xedil), the provoked potentials were led from
ventral posterior lateral part of the thalamus
secondary somato-sensory region of the cortex
he right hemisphere, where the central ends
he mesenteric nerves and mechanoreceptors of
stomach and large intestine were stimulated.
he part of the nucleus, limited by coordinates
per and Ajmone-Marsan, 1955) frontally from
10.0, laterally from 5.5-8.5 and by vertically
+3.0 to +1.0 (above 0 horizontal) provoked
potentials appeared during the stimulation of nerves and receptors; most often the focus of max. activity was determined in the central part of the nucleus on frontal coordinates, 8.5-9.0, lateral, 7.0-7.5, and vertical, 2.5-1.0. Its location, however, varied and in some experiments was located on other coordinates. Simultaneous recording of responses in the thalamus and cortex during stimulation of mesenteric nerves showed that the potentials appearing in both regions are identical in form and time parameters. The latent period of thalamic response in the focus of max. activity during mesenteric nerve stimulation is 2-3 msec. shorter than the latency of cortical responses in the focus of max. activity in the second projection zone. The provoked potentials had a biphasic form and started with positive oscillation, which was replaced by a negative. Duration of the first phase was 23-30 msec. The form of responses of the ventral posterior lateral part of the thalamus, their time parameters and relation to rhythmical stimulation give reason to regard them as primary, and the region of the nucleus in which they appeared as the projection region of the mesenteric nerves. Stimulation of gastric and large intestine mechanoreceptors by balloon produced a series of provoked potentials. Each single potential in series could be identified by form and some time parameters with the primary response, which appeared on stimulation of mesenteric nerves. The potentials in the thalamus appeared simultaneously with provoked potentials of the cortex, in these cases, when both electrodes were in the foci of max. activity. The frequency of the series of potentials in the responses of the thalamus and cortex was 2-3 per sec.; this frequency was optimal for the responses of cortex and thalamus during electrical stimulation of the nerves. In experiments with stimulation of thalamus, responses in the cortex could appear also during frequent stimulation of the thalamus. On the basis of these it is concluded that the conversion of continuous afferent impulses, going from the receptors during stimulation of internal organs, into slow rhythmical activity of the cortex does not originate in the thalamus.

SILICONE-FOAM MOLDING OF THE CANINE
ILEOCOLONIC JUNCTIONAL ZONE. (E.)
, M. L., Jr. (U. Rochester Sch. Med., N. Y.),
Gordon, R. Terry and J. A. DeWeese. Amer.
. Dis. 12(8):813-822, 1967.

of the isolated ileocolonic junctional area
ade in 61 dogs (2 conscious, 6 anesthetized
immediately after death) by the forceful
nto the proximal colon of a mixture of ex-
g silicone-foam rubbers; the latter were
ng polysiloxane elastomers which, when
rized, changed from liquid to the solid state
oduced synthetic foam-rubber casts. An
constriction (mean width, 0.83 ± 0.067;
ength 0.40 cm ± 0.026) was consistently
trated on the molds at the junction of the
nd large intestine. A similar ring-like
ion (mean width, 1.14 cm ± 0.060; mean
0.31 cm ± 0.028) occurred at the point
ing of cecum and colon. The configuration
molds at both junctional zones indicated
sence of a narrow band of less distensible
ne at these sites. Dimensions of the ileum,
nd cecum were, resp., 1.62 ± 0.05 (range
3 cm), 2.47 ± 0.09 (range 0.8-3.8) and
0.04 (range 1.1-2.7 cm). Microscopic
tion of the tissue producing the indenta-
the ileocolonic junction showed that the
was composed of smooth muscle derived from
er circular muscle coat of the ileum and
coated by a transitional colonic type of epithelium. This intraluminal projection conformed to the morphological definition of a sphincter; the anatomical narrowing probably is at least partially responsible for a zone of elevated pressure interposed between the small and large intestine.

9741 OUABAIN EFFECT ON TRANSMURAL TRANSPORT OF POTASSIUM BY CANINE SMALL INTESTINE.

(E.) Weiner, D. E. (U. Virginia Sch. Med., Charlottesville). Proc. Soc. Exp. Biol. Med. 125(2):648-651, 1967.

Isolated preparations of jejunal mucosa were obtained from fasted dogs, and incubated in a modified Krebs-Henseleit bicarbonate buffer containing 10 mM glucose, 140 mM Na ion and 12 mM K ion. ^{42}K was added to the incubation soln. to serve as a tracer for K movement. All jejunal membranes were mounted in pairs, and at the end of an equilibration period of 30 min., ouabain (10^{-5} M) was added to 1 of the pairs. In separate experiments, the flux of K into the cell interior was measured by labeling the incubation soln. facing 1 cell surface with ^{42}K and labeling the other soln. with ^{86}Rb. Ouabain affected K transport only when added to the serosal incubation soln.; addition to the luminal incubation soln. was without effect. Ouabain at a conc. of 10^{-6}M altered K transport, but the onset of peak activity occurred late, at 60-90 min. after addition of the agent. Ouabain markedly accelerated the K transmural influx (mucosal to serosal soln.) across the mucosal membrane, the difference between control and ouabain being statistically significant; the small decrease in transmural potential in the presence of ouabain was not statistically significant. K permeability of the mucosal and serosal cell surfaces in the presence and absence of ouabain showed that the latter did not affect the influx across the luminal cell surface, but did significantly decrease the influx across the serosal cell surface. These results suggest several conclusions concerning the transport of K by the small intestinal mucosal cell. It appears likely that K actually passes through the cell, rather than passing through extracellular channels between cells, as has commonly been suggested. This alteration in cellular K transport appears to be carrier-linked, and the carrier involved in the ouabain-enhanced transmural flux is on the serosal surface of the mucosal cell. Since K cannot be shown to be transported against an electrochemical gradient and K transport has a low Q_{10} suggestive of a diffusion process, the carrier process involved in K transport may be an example of an equilibrating carrier system. Whether K has a carrier mechanism regularly available, or whether it is able to use the Na carrier when the latter is altered by addition of ouabain to the system, is an important question which remains to be answered.

9742 ROLE OF INTRALUMINAL PRECIPITATION IN SECRETION OF SMALL INTESTINAL CALCIUM AND PHOSPHATE IN THE DOG.

(E.) Schedl, H. P. (U. Iowa Coll. Med., Iowa City), G. W. Osbaldiston and I. H. Mills. Nature (London) 215(5097): 198-199, 1967.

The hypothesis that Ca exists in more than 1
phase was examined, and the following parame
tested: 1) the Ca composition of endogenous
intestinal secretions, and 2) the Ca and pho
phate content in the lumen 30 min. after a
dilute Ca soln. had been introduced into clo
segments of small intestine. Two adjacent
jejunal and 2 adjacent ileal segments were p
pared in situ in each of 17 fasted, anesthet
dogs; each segment was approx. 20 cm long ar
contained 2 arcades of mesenteric vessels.
all were prepared, the 4 segments were flush
as quickly as possible with 200 ml of saline
followed by air. In 5 dogs, no soln. was in
duced, the empty segments were left in situ
1 hr. and the endogenous secretion was colle
by washing with 25 ml of 5% mannitol. In 12
dogs, 10 ml of a soln. containing 1 mg of Ca
(as $CaCl_2$) and 100 mg of inulin was immediat
introduced; after 30 min. the luminal conten
were collected and analyzed for Ca, inulin a
phosphate. All samples contained a small
porportion of precipitate. Inulin was virtu
unabsorbed during a 30-min. period. Endogen
Ca entered empty segments and was not homoge
Ca was present both in soln. in the superna
and in the form of an acid-soluble precipit
Thirty min. after the Ca soln. was introduc
intraluminal contents were also in 2 phases
Ca and phosphate were present in the precip
but the proportion of precipitated Ca was m
lower than in the empty segments. The acid
soluble precipitate was not identified, but
acidification, bubbles of gas were evolved,
suggesting that the precipitate was, at lea
part, a $CaCO_3$ or $Ca(HCO_3)_2$ complex.

9743 DUODENAL CALCIUM TRANSPORT IN HYP
THYROIDISM.

(E.) Krawitt, E. L.
Iowa Coll. Med., Iowa City). Proc. Soc. Ex
Biol. Med. 125(2):417-419, 1967.

The influence of hyperthyroidism on intesti
Ca absorption was studied with an in vivo
perfusion technic in the rat duodenum. Mal
Sprague-Dawley rats were made hyperthyroid
daily inj. with 125 µg of l-thyroxine for 1
days; during the 2 wk. prior to study, all
animals were fed laboratory chow containing
Ca. The duodenum was perfused with fluid f
reservoir containing 17 ml of soln. by re-
circulation at a rate of 1.8 ml/min. for 2
using a proportioning pump; the perfusing s
of pH 6.5 contained 1.7 mM $CaCl_2$, 141 mM Na
10 mM 1;1:1-tris (hydroxymethyl) methylamin
0.2% polyethylene glycol and 0.01 µc ml ^{45}C
Animals which received the daily inj. of l-
thyroxine suffered a loss of body wt. of ap
5%, as well as developing weakness, diarrhe
alopecia. The mean 2-hr. absorption rate o
was 11.5 ±2.8 µmol/g wet wt. of intestine f
hyperthyroid animals, compared with a mean
14.7±4.0 for controls. Mean lumen to plasm
flux in hyperthyroid rats was 14.6±4.0, whi

of controls 19.0±4.8. The plasma to lumen
means were 3.1±1.4, and 4.3±2.5 for hyper-
oid and control rats, resp. The last 2
, although slightly decreased, were not
stically significantly different in hyper-
oid rats compared to normal control animals.
findings do not support the hypothesis of
ased Ca absorption in the duodenum as a
factor contributory to the increased fecal
tion of Ca seen in hyperthyroid rats.

PASSAGE OF RADIO-IODINATED INSULIN THROUGH THE INTESTINAL WALL OF THE RAT.

D'Addabbo, A. (U. Bari, Italy), G. Fanfani
. Muscogiuri. Diabetologia (Berlin) 3(3):
10, 1967.

ulin was admin. i.v. to normal rats, and
assage of radioactivity into the duodenal
containing a protease inhibitor (Trasylol)
tudied by 2 technics. In the first, the
insulin was separated from the intestinal
nt by electrophoresis; in the second, the
activity that remained on an ion-exchange
, directly introduced into the small
tine, was measured. Within 15 min. after
a small amount of ^{131}I-insulin passed into
ntestinal lumen. The absorption of ^{131}I-
in from the small intestine into the blood
tudied after introduction of ^{131}I-insulin
with Trasylol into the intestinal loop.
adiography of the electrophoresis of serum
d plasma-protein-bound radioactivity, but
dioactivity due to unbound (free) ^{131}I-insulin.
findings reveal that the passage of insulin
gh the intestinal wall of rats can be
strated by neutralizing the proteolytic
ity in the intestinal tract. Insulin, like
other proteins, passes across the intestinal
and a 2-way movement of this molecule is
ble.

EFFECT OF INTESTINAL CONTENTS ON UPTAKE OF RADIOIRON BY EVERTED RAT GUT SACS.

Murray, J. (U. Minnesota, Minneapolis) and
ein. Proc. Soc. Exp. Biol. Med. 125(2):
3, 1967.

vitro uptake of ^{59}Fe (ferrous citrate) by
d gut sacs from fasted and nonfasted
e-Dawley rats was studied using several
of secretions; the first 20 cm of intestine
the pylorus was used to provide 4 seg-
of 4 cm from each rat. Segments were
exposed to the prepared secretion or test
al at 37°C for 30 min., then washed in
ld phosphate buffer at pH 7,2; the uptake
e by the segments as ferrous citrate was
etermined and recorded as an index of
. The following 11 parameters were stu-
1) sacs from unfasted rats; 2) sacs from
ted fasted rats; 3) sacs from fasted rats
ated with Laboratory Chow; 4) sacs from
rats pretreated with intestinal wash from
rats given pancreozymin, secretin and histamine; 5) sacs from fasted rats pretreated with intestinal wash from fasting rats; 6) sacs from fasted rats pretreated with boiled intestinal wash; 7) sacs from fasted rats pretreated with ascorbic acid; 8) sacs from fasted rats pretreated with stomach contents from unfasted rats; 9) sacs from fasted rats pretreated with stomach contents from fasted rats; 10) sacs from fasted rats pretreated with stomach contents from fasted rats given histamine; and 11) sacs from fasted rats pretreated with intestinal wash from unfasted rats. Intestinal contents from fasted animals had no significant effect on uptake of ^{59}Fe by intestinal sacs from fasted rats, but intestinal contents from unfasted animals increased the index considerably. Stomach contents from fasted rats or from rats stimulated with histamine also increased the indices, but not as greatly as unfasted intestinal contents. No other test soln. had a significant effect on the segments and boiling destroyed the ability of unfasted intestinal contents to potentiate Fe absorption. Sacs from unfasted rats without pretreatment with test soln. also showed considerable increase in uptake over segments from fasted rats. Several deductions can be made from these experiments. There is a factor in intestinal contents of feeding animals that facilitates the uptake of Fe by everted intestinal sacs, and there is a factor in neutralized gastric juice from fasted animals or animals stimulated with histamine which has a similar, but less powerful, effect. The gastric factor is not the same as the intestinal factor, since the latter appears only in the feeding animals and the former in fasting or stimulated animals. Pancreozymin, plus secretin, plus histamine stimulation of fasting animals does not potentiate Fe absorption, thereby suggesting that pancreatic secretions alone do not influence Fe absorption in sacs. The intestinal factor appears to be the result of the action of intestinal secretions on food and can be destroyed by heat. It is emphasized that these findings are strictly in vitro observations.

9746 TRANSPORT OF BASIC AMINO ACIDS BY HAMSTER INTESTINE.

(E.) McLeod, M. E. (Duke U. Med. Ctr., Durham, N. C.) and M. P. Tyor. Amer. J. Physiol. 213(1):163-168, 1967.

In sequential sections of small intestine derived from male golden hamsters, chromatographic analysis of serosal fluid from everted tissue sacs and extracts from tissue segments, following incubation with ^{14}C-labeled L-arginine, L-lysine and DL-ornithine, showed that transport against a chemical conc. gradient was demonstrable with respect to all 3 amino acids throughout the entire length of the small intestine. Following incubation with L-arginine, considerable radioactivity was found in urea cycle metabolites other than arginine, decreasing progressively in segments derived sequentially from the pylorus to the cecum. Considerably less metabolic transformation was evidenced with respect to DL-ornithine, while essentially all radioactivity was present as lysine after incubation with L-lysine, whose rate of transport was substantially identical throughout the entire length of the small intestine when only tissue segments were analyzed. However, the distal intestine was the site of max. transport for all 3 basic amino acids, when the tissue sac technic was employed.

9747 INTRINSIC FACTOR-MEDIATED ATTACHMENT OF VITAMIN B_{12} TO BRUSH BORDERS AND MICROVILLOUS MEMBRANES OF HAMSTER INTESTINE. (E.) Donaldson, R. M., Jr. (U. Wisconsin Med. Sch., Madison), I. L. Mackenzie and J. S. Trier. J. Clin. Invest. 46(7):1215-1228, 1967.

The uptake of ^{57}Co-labeled cyanocobalamin by the brush borders and microvillous membranes of the distal half of the hamster intestine was increased by hamster intrinsic factor preparations. A corresponding effect was observed using rabbit and rat intrinsic factor preparations. Preparations obtained from dog, hog and man were ineffective. Vitamin B_{12} uptake by the brush borders correlated well with the vitamin B_{12}-binding capacities of different fractions of intrinsic factor obtained by either gel diffusion or ion exchange chromatography. Vitamin B_{12} uptake mediated by intrinsic factor occurred rapidly, was unaffected by removal of glucose or O_2 and lowering of the incubation temperature. Pronounced reduction in uptake occurred with the absence of divalent cations. Preincubation of proximal brush borders with the supernatant obtained from the centrifugation of distal segment preparations resulted in an increased vitamin B_{12} uptake. Decreased uptake and lysis of brush borders resulted from prolonged incubation of brush borders with crude saline extracts of hamster gastric mucosa. Increased purity of intrinsic factor preparations resulted in higher uptakes of vitamin B_{12}. These findings give greater support for the presence of a specific receptor for intrinsic factor-bound vitamin B_{12} at the microvillous surface of the intestinal cell.

9748 SOME PHYSIOLOGIC PROPERTIES OF HETEROTOPIC INTESTINAL EPITHELIUM. ITS ROLE IN TRANSPORTING LIPID INTO THE GASTRIC MUCOSA. (E.) Rubin, W. (Cornell U. Med. Coll., New York, N. Y.), L. L. Ross, G. H. Jeffries and M. H. Sleisenger. Lab. Invest. 16(6):813-827, 1967.

Biopsies of normal gastric mucosa from 9 of 10 fasting subjects showed no significant mucosal lipid after oil red O staining; the tenth exhibited a few lipid droplets within surface mucous cells. By contrast, gastric biopsies from 4 of 5 patients with intestinal metaplasia exhibited significant amounts of lipid in the lamina propria adjacent to surface heterotopic intestinal cells, particularly along surface
villi; the lipid-free biopsy from the fifth
patient had only a few intestinal-type cell
the surface. On 3 separate occasions, 1 of
lipid preparations (micellar lipid, an eggn
and linseed oil) was infused into the stoma
of a patient with extensive heterotopic int
tinal epithelium. Biopsies obtained before
sequentially after each infusion were stain
for lipid and examined by light and electro
microscopy. Surface heterotopic intestinal
epithelial cells transported large amounts
micellar lipid and significant but smaller
amounts of linseed oil or eggnog lipid from
gastric lumen. The morphologic phenomena
exhibited by the heterotopic epithelium dur
lipid transport appeared identical to those
exhibited by normal jejunal epithelium. Si
cant amounts of lipid could not be detected
within surface cells of gastric type after
micellar lipid instillation, but occasional
lipid droplets were noted after linseed oil
eggnog. These findings indicate that heter
intestinal epithelium is similar to normal
jejunal epithelium in its physiologic prope
Its presence within the gastric mucosa prob
changes this primarily secretory tissue to
that is more absorptive in nature. This
physiologic transformation may play a signi
role in the pathogenesis of diseases with
intestinal heterotopia is associated.

9749 EFFECT OF STIMULATION OF DIFFEREN
BRAIN CORTEX REGIONS ON LIPID ABS
IN THE GASTROINTESTINAL TRACT. (Uk.)
Faitelberg, R. O. (Mechnikov State U., Ode
USSR) and L. P. Nikiforova. Fiziol. Zh.
13(3):332-337, 1967.

Changes of lipid absorption in the gastro-
intestinal tract could be provoked by the
stimulation of different regions of the do
cerebral cortex. During stimulation of th
twenty-first field of the temporal region
the cerebral cortex with a current of 0.5
lipid absorption was decreased during the
4 hr. of the experiment, while at stimulat
with a current of 1-2 volt, lipid absorpti
changed slightly. With stimulation of the
eighteenth field of the occipital region o
brain by a current of 0.5-1.0-2.0 volts,
absorption in the gastrointestinal tract
decreased for 6 hr. At stimulation of the
seventh field of sincipital region of cere
cortex, the lipid absorption was markedly
creased only under the action of a current
1-2 volt. At stimulation of the sixth fie
the frontal region of the cerebral cortex
a current of 0.5-1.0-2.0 volt, lipid absor
substantially decreased. Mechanical stimu
of the dura mater of the occipital region
accompanied by a marked increase of lipid
absorption during the first 4 hr.

9750 PROPERTIES AND METABOLISM OF 2-A
KANOATES. III: ABSORPTION OF M

HYL 2-METHYLPALMITATE. (E.) Saladin,
(U. Michigan Med. Sch., Ann Arbor) and
Napier, Jr. *J. Lipid. Res.* 8(4):342-349,

ery from rat and rabbit tissues of fed methyl-
d ethyl-2-^{14}C 2-methylpalmitate with un-
d specific activity demonstrated the exis-
of mechanisms for the absorption and deposi-
f both methyl and ehtyl esters of fayyt acids,
st for 2-methylpalmitate. In thoracic duct-
ated rats, approx. 9% of the fed compounds
covered from the lymph during the first
; the rate of recovery reached a max.
n 6 and 8 hr. In the rabbit, the fed,
red esters in plasma were transported
pally by means of the low density lipoprotein.
r, only trace amounts of the unaltered
were subsequently detected in the blood
ssue lipids after feeding, even during the
of max. absorption; moreover, in contrast
least 1 report in the literature, further
es for methyl or ethyl esters of other
acids revealed that such esters of short-
alcohols constitute no more than a trace
(0.004-1.03%) of the lipids extracted
wide variety of mammalian tissues. It is
le that even these trace amounts of esters
as artifacts of autolysis, assay or
tion.

A SIMPLE TECHNIC FOR STUDYING INTESTINAL
ABSORPTION IN THE NURSING INFANT.
PTION OF LACTOSE IN NORMAL AND DYSTROPHIC
TS. (It.) Giunta, A. (U. Milan, Italy)
Porta. *Minerva Pediat.* 19(17):866-869,

tinal absorption was studied in 6 normal
g infants (8-18 mo. old) and in 9 dystro-
ursing infants (10-16 mo. old) according
e following simplified technic: introduction
gh the nasal route of a duodenal catheter
bulb measures 7 mm in diameter just past
igament of Treitz (under fluoroscopic con-
and subsequent p.o. admin. of a test meal
sed of protein (casein and lactalbumin)
; 22.3 g; fat (olive oil) 18.7 g lactose;
; sucrose; 18.7 g; maltose 4 g polyethylene
; 295 g water. Samples of intestinal con-
were obtained at 0, 30, 60, 90, 120, 150,
80 min. after feeding, and their lactose
lycol contents determined according to the
tröm method. Blood glucose curves were also
mined at 30-min. intervals 0-2 hr. after
ng. No difference was observed in the
glucose curves and glycol content between
groups. Dystrophic infants, however,
led a progressive decrease in lactose
ption as compared to normal infants; this
bly represents an exhaustion on the part
e enzyme systems concerned with lactose
down and absorption. The consistency of
values in these infants excludes the
bility of a difference in intestinal transit
e test meal. Correlation coefficients were barely significant: normal = 0.722 and dystrophic infants = 0.436. The above method is considered suitable for the determination of intestinal disaccharide absorption, but a greater number of tests must be conducted in order to obtain an accurate picture.

9752 THE ABSORPTION OF MALTOSE AND LACTOSE IN MAN. (E.) McMichael, H. B. (St. Bartholomew's Hosp., London), J. Webb and A. M. Dawson. *Clin. Sci.* 33(1):135-145, 1967.

The technic of jejunal perfusion was used to study the absorption of maltose and lactose in 20 subjects (16 men, 4 women; 18-62 yr. old) who were being studied for abdominal pain or diarrhea, and all of whom had a structurally normal jejunum. Of these, 3 had peptic ulcer, 5 had previous gastric surgery, 2 had ulcerative colitis and 1 had pancreatic steatorrhea; of these 11, 1 had lactase, sucrase and palatinase deficiencies, and 2 had lactase deficiency. Among the 9 subjects with no demonstrable organic lesions, 6 had lactase deficiency. The kinetics of absorption and hydrolysis were calculated from observations using 4 different conc. (1.25, 2.5, 5.0 and 10.0 g/100 ml) of perfused sugars. Total hydrolysis of lactose was less than that of maltose, but it only became rate-limiting for absorption in subjects with constitutional hypolactasia. Max. hydrolysis of disaccharide was observed at low levels of mucosal disaccharidase, and it is suggested that hydrolysis may not only be limited by mucosal disaccharidase activity. Absorption rates of glucose and maltose from soln. rendered isotonic with NaCl were the same; this shows that intraluminal Na conc. does not alter the rate of sugar absorption under the conditions of these experiments.

9753 INTESTINAL ABSORPTION OF SUGARS IN SEMI-STARVED RATS. (E.) Esposito, G. (U. Kentucky Coll. Med., Lexington). *Proc. Soc. Exp. Biol. Med.* 125(2):452-454, 1967.

Male Sprague-Dawley rats were divided into 2 groups, and were fed either *ad libitum* or food at 8 g/day/rat (semistarved group). At the end of 15 days of special feeding, absorption studies were performed *in vivo* by perfusion of a loop of upper jejunum with 50 ml of isosmotic Na_2SO_4 soln. containing either glucose or 3-0-methylglucose. Both of the latter 2 agents were present in the perfusing fluid in 2 initial conc.: 50 mg% (approx. 3.1 mM or 2.6 mM, resp.) and 150 mM. At low lumenal conc., glucose disappeared significantly faster from the intestine of semistarved rats than from the controls (normally fed). Phlorhizin in low (10^{-4} M) conc. strongly inhibited glucose absorption from the intestine of both control and semistarved animals. However, absorption of the non-metabolizable sugar, 3-0-methylglucose was not influenced by previous semistarvation. When the sugar was offered in high (150 mM) conc., there was a slight increase in rate of absorption of both glucose and 3-0-methylglucose from the intestine of semistarved animals, but the statistical validity of this difference was highly questionable. It is suggested that semistarvation influences glucose absorption by modifying its intestinal metabolism, rather than by acting directly upon the transport mechanism.

9754 THE PORTAL TRANSFER OF GLUCOSE IN THE DOG. (E.) Varró, V. (U. Med. Sch., Szeged, Hungary) and L. Csernay. Amer. J. Dig. Dis. 12(8):775-784, 1967.

The quantitative conditions and dynamics of the portal transport of absorbed glucose were studied in the dog; a 10-15 cm long segment of proximal jejunum was isolated, and absorption and portal transport of isotonic glucose soln. introduced into the intestinal lumen was assessed; absorption was measured by the difference in the amount of sugar introduced and the amount retained, i.e., the amount of glucose (in mg) that disappeared from the lumen during a 15-min. experimental period. Considerable differences existed among individual animals as to rate of portal transport of glucose; this variation seemed to be determined by the metabolic conditions of the small intestine. In most of the animals, the amount of transported glucose ranged between 40-80%, but smaller and larger transport rates were also noted; in 18 animals, glucose transport was greater than 90%, even exceeding the amount of absorbed sugar. The amount of transported glucose was directly proportional to the arteriovenous glucose difference. A similar, but less direct, relationship was observed between corresponding values of glucose transport and intestinal blood flow. A considerable quantity of glucose was found to be transported during the first 3 min.; after glucose soln. was washed out of the intestine, little sugar transport was demonstrated, even during the first 5-min. period of study. In several animals the transport rate in a proximal jejunal segment was measured, as well as in a distal ileal loop. The same differences in transport values that occurred in study of portal transport were detected in both the jejunal segment and the ileal loop; no essential difference was observed between the percentage values of the jejunal and ileal transport.

9755 SMALL BOWEL GLUCOSE ABSORPTION IN RATS ON INHALING VARIOUS GAS MIXTURES. (Rus.) Amirov, N. Sh. (Inst. Normal & Path. Physiol., Moscow). Fiziol. Zh. SSSR Sechenov 53(6):705-710, 1967.

Glucose absorption from the small intestine with increased O_2 content in the gas mixture (up to 60%), at decreased content of O_2 (to 10%), normal O_2 content and increased CO_2 (from 5-35%) content was studied in male rats (180-200 g). Glucose absorption during the respiration of the
O_2 mixture was increased. With respiration c
the hypercapnic mixture of 5-35% CO_2 and 21%
the same increase of absorption was noted; at
5-10% CO_2, this increase was not reliable, wh
at 15-30% it was reliable. The increase of
absorption at 35% CO_2 conc. as well as the
decrease of absorption at respiration of low
mixture (10% O_2, 90% N_2) was not significant.
During respiration of a mixture containing 60
O_2 the blood O_2 level increased by about 10%
while during respiration of hypercapnic and l
O_2 mixture the latter was decreased. However
the decrease in glucose absorption during
respiration of the low O_2 mixture was not
significant, and during respiration of the
hypercapnic mixture the absorption increased.
Blood (portal vein) sugar level increase duri
respiration of the high O_2 mixture was relial
while the increase at 5% CO_2 and the decrease
10% CO_2 were not reliable. During respiratio
of the gas mixture containing 15-35% CO_2 or
during respiration of the low O_2 mixture the
blood sugar level decrease was reliable. Blo
(portal vein) lactic acid increase during glu
absorption was significantly lower in high O_2
and hypercapnic conditions and was unchanged
under low O_2 conditions when compared to controls. It is concluded that O_2 has an essent
role in intestinal absorption.

9756 INTESTINAL TRIGLYCERIDE ABSORPTION
THE RAT. AN ELECTRON MICROSCOPICAL
STUDY. (E.) Cardell, R. R., Jr. (Harvard U.
Cambridge, Mass.), S. Badenhausen and K. R.
Porter. J. Cell Biol. 34(1):123-155, 1967.

Fat absorption by the rat intestine was inves
tigated by 3 methods: Intubation of corn oil
into fasted animals; inj. of physiologic fatt
chyme prepared from fat-fed donor rats into
ligated segments of jejunum of fasted animals
by admin. of electron-opaque particles in cor
oil and markers given concurrently with the f
The results obtained do not support pinocytos
an important process in fat absorption and th
is doubt expressed as to whether pinocytosis
functions at all. It is suggested that fat i
absorbed by selective diffusion of monoglycer
and fatty acids from micelles rather than by
pinocytosis of unhydrolyzed triglycerides. D
pressions between the microvilli are not invo
in the transport of fat, as had been supposed
Rather, they appear to pass on their contents
lysosomes in the apical cytoplasm. Monoglyce
and fatty acids diffuse from the micelle at a
time when it is associated with the microvill
membrane of the absorptive cell. Micellar co
ponents penetrate the plasma membrane diffusi
into the cytoplasmic matrix where they contac
the smooth endoplasmic reticulum in which tri
glyceride synthesis occurs, resulting in the
deposition of fat droplets within its lumina.
Triglyceride synthesis and sequestration into
the smooth endoplasmic reticulum establishes
inward diffusion gradient of monoglycerides a
fatty acids.

9766 PROGRESSIVE SYSTEMIC SCLEROSIS: I. GASTRIC SECRETORY PATTERN. STUDY UNDER BASAL CONDITIONS AND AFTER BETAZOLE HYDROCHLORIDE (HISTALOG) MAXIMAL STIMULATION.

(E.) Bettarello, A. (Med. Sch., Sao Paulo, Brazil), D. P. Neves and S. Zaterka. Amer. J. Dig. Dis. 12(8): 804-807, 1967.

Gastric secretory patterns were assessed in 24 patients (19 female, 5 male; 21-56 yr. old, with a mean age of 34.4 yr.) with progressive systemic sclerosis; 20 of them had an esophageal and/or gastroduodenal complaint (heartburn in 16, dysphagia in 13, regurgitation in 9, retrosternal pain in 3, epigastric pyrosis in 13, nausea and vomiting in 11, and epigastric pain in 8). Upper gastrointestinal X-ray examinations failed to disclose peptic ulcer in any patient; in 3, dilatation of the second and third portions of the duodenum was observed, and in a fourth patient, gastric ectasia was noted. Esophagitis was present in 13 of 22 patients in whom esophageal biopsy was performed; in 10 patients with esophagitis, a positive Bernstein test was observed. Gastric secretion was studied under basal conditions and after betazole stimulation. Controls were 20 healthy people (10 of each sex) with no digestive complaint. No staistically significant difference was observed in the gastric secretory pattern between both groups. Esophagitis in patients with progressive systemic sclerosis is not related to the degree of acid output by the stomach, and it is concluded that esophagitis is probably the result of regurgitation of gastric juice of normal or even low acidity to an already-weakened esophageal mucosa.

9767 INFLUENCE OF HISTAMINE ON PEPSIN SECRETION IN HUMANS.

(Uk.) Fisher, A. A. (Kuban Med. Inst., Krasnodar, USSR). Fiziol. Zh. (Kiev) 13(3):405-408, 1967.

Group 1 consisted of 15 healthy persons (12 males, 3 females; age 17-53 yr.), Group 2, 15 patients (13 males, 2 females) with gastric ulcer, and Group 3, 55 patients (50 males, 5 females) with duodenal ulcers. Histamine did not reduce pepsin conc. in the gastric juice; max. conc. was found in all persons in the first 30 min. after admin. of histamine (0.1 mg/10 kg body wt. of 0.1% soln., s.c.), and in the patients, as a rule, in the first 15 min. In Group 1, max. pepsin conc. exceeded the basal level by an av. of 2.75 times, in Group 2 by 1.75 times and in Group 3 by 1.34 times. At the end of 1 hr. after stimulation the pepsin content reached initial values in the patients and exceeded almost 1.5 times that in healthy persons. Av. pepsin (in mg/30 min.) or acid (in mEq per 30 min.) yield in basal secretion (15+30 min.) was 6.89 or 1.06 in Group 1, resp., 28.79 or 2.52 in Group 2, resp., in Group 3, 46.76 or 6.09, resp.; 45 and 60 min. after histamine stimulation it was in Group 1, 44.68 or 6.27, resp., in Group 2, 61.13 or 7.19, resp.,
in Group 3, 80.0 or 11.76, resp.; 75 and 90
after histamine stimulation was in Group 1,
31.46 or 5.23, resp., in Group 2, 37.08 or
resp., in Group 3, 51.09 or 9.70, resp.; an
yield ratio for $\frac{(45+60\ \text{min.})}{(15+30\ \text{min.})}$ was in Group 1
or 5.9, resp., in Group 2, 2.1 or 2.8, resp
Group 3, 1.7 or 1.9, resp.; for $\frac{(75+90\ \text{min.}}{(15+30\ \text{min.}}$
was in Group 1, 4.6 or 4.9, resp., in Group
1.3 or 2.1, resp., in Group 3, 1.1 or 1.6,
Therefore, in man, histamine provoked stimu
of peptic secretion to the same degree as a
at unchanged or increased gastric secretory
function; the degree of increase in pepsin
secretion was higher the lower its level be
stimulation.

9768 COMPARATIVE STUDY OF GASTRIC SECRE FOLLOWING THE ADMINISTRATION OF HISTAMINE, BETAZOLE HYDROCHLORIDE, AND A MI OF AMINO ACIDS.

(It.) Dal Monte, P. R. (U
Bologna, Italy), E. Fiore, L. Lodi and R.
Cremonini. Boll. Soc. Ital. Biol. Sper. 43
154-157, 1967.

The effects of histamine (0.02 mg/kg), beta
hydrochloride (1 mg/kg), and a mixture of a
acids (450 mg in 50 ml H_2O) on gastric secr
were investigated in 15 subjects without ga
intestinal disturbances. The above agents
admin. at intervals of 24 hr. from each oth
gastric juice samples were collected before
treatment and at 15-min. intervals over a p
of 1 hr. The vol., pH (Beckmann pH meter),
HCl content of the gastric juice were deter
for each sample. The av. vol. after 1 hr.
greatest following betazole (49 ml), slight
less following histamine (48 ml), and least
after amino acid mixture (23 ml). The high
level of gastric secretion was observed aft
min. (65 ml) with the amino acid mixture, a
30 min. (62 ml) with betazole, and after 1
with histamine. At the end of 1 hr., HCl c
was greatest after betazole (5.28 mEq), sli
less following histamine (4.8 mEq), and lea
after the amino acid mixture (1.3 mEq). Ma
HCl conc. was observed after 30 min. with b
(6.3 mEq) and amino acids (2.6 mEq), and af
1 hr. with histamine. The pH curves for hi
and betazole showed the same progressive de
from basal (3.4 and 2.7, resp.) to 1 hr. va
(1.2 in both cases); pH curves after amino
increased from a basal 3.0 to 3.2 after 15
then progressively decreased to 1.7 after 1
Comparison of results indicates that those
substances which are particularly active on
gastric mucosa (histamine and betazole) exe
stronger effect on gastric secretion than d
the amino acid mixture, which represents, h
ever, a physiological stimulus. Betazole i
better stimulating agent than histamine ina
as it is more potent, causes fewer side eff
and does not reqnire antihistamine protecti

769 EXPERIMENTAL STUDY CONCERNING THE
EFFECT OF ASSOCIATED RESERPINE AND
)LBUTAMIDE ON GASTRIC ACTIVITY. (Rum.)
hăilescu, M. (Institute of Medicine Pharmacol.
ab., Timisoara, Rumania). Fiziol. Norm. Pat.
2(5):443-448, 1966.

ngle or repeated (7-14 days) admin. of reser-
ine (0.0005-0.005 g/kg, i.p. or i.m. inj.) in
bino rats (200-250 g body wt.) increased av.
astric secretion to 2.1 ml within 7 hr. as com-
ared to 0.4-1.1 ml in controls. For tolbutamide
).1-0.5 g kg, p.o.) the av. gastric secretion
as 1.9 ml (5-7 hr.) while for associated admin.
f tolbutamide and reserpine the gastric secre-
ion amounted to 3.4 ml. Gastric acidity varied
arallel with the gastric secretion and was 37
Eq/liter for reserpine, 41 mEq/liter for tolbut-
mide and 49 mEq/liter for reserpine and tolbut-
mide; the gastric acidity in controls was
3 mEq/liter. Av. gastric-wall cholinesterase
ctivity following repeated admin. of tolbutamide
r reserpine was 55 U as compared to 43.5 U for
olbutamide and reserpine and to 70 U in controls.
astric ulcerations were noted in 58% of the
nimals receiving repeated treatment with reser-
ine while 27% of the rats receiving tolbutamide
nd 94.5% of those given reserpine and tolbutamide
ad stomach ulcerations. The number of ulcera-
ions was approx. 3 times greater (11-14) in
nimals treated with tolbutamide and reserpine
han in those given reserpine (3-5 ulcerations).
he functional and pathological changes suggest
hat extreme caution and continuous control must
e exerted in the prescription and admin. of the
gents studied.

770 THE ACTION OF RESERPINE ON GASTRIC
SECRETION. (E.) Schapiro, H. (U.
'ennessee Med. Units, Memphis). Arch. Surg.
(Chicago) 95(1):144-150, 1967.

he i.m. inj. of 0.5 mg of reserpine into human
ubjects (11 patients with duodenal ulcers, 3
ith gastric ulcers and 9 subjects with no gastro-
ntestinal complaints) caused, after a 30- to 45-
in. latent period, a gastric hypersecretion that
asted longer than 6 hr.; this reserpine-induced
gastric hypersecretion was not altered by bilateral
vagotomy, bilateral thoracolumbar sympathectomy, or
by gastric antrectomy. The i.v. inj. of 0.025-
).075 mg/kg of reserpine into dogs caused, after
a 30- to 45-min. latent period, a marked gastric
hypersecretion that lasted longer than 24 hr.; this
reserpine-induced gastric hypersecretion was not
max., for s.c. inj. of histamine at varying inter-
vals of time always caused a further increase in
gastric secrtion. Gastric hypersecretion caused by
reserpine in dogs could not be abolished by bila-
teral vagotomy, gastric antrectomy, bilateral
thoracolumbar sympathectomy, surgical resection of
the small intestine and colon, hypophysectomy,
or bilateral adrenalectomy. In studies with
antihistamines, 50 mg/kg of diphenhydramine did
not alter gastric hypersecretion induced by
reserpine. Very high conc. of anticholinergic
drugs could only reduce this gastric hypersecretion by 70-75% for 4 hr., after which time this gastric hypersecretion resumed; atropine (0.4-0.6 mg/kg) reduced the gastric response by 69%, hexamethionium (10 mg/kg) reduced it by 50%, and oxyphenonium (0.5-1.0 mg/kg) reduced the response by 75%. Neither sodium pentobarbital anesthesia nor spinal cord section at the C_1-C_2 level altered this gastric hypersecretion. However, this reserpine-induced gastric hypersecretion was abolished in 5 dogs in which the cerebral circulation was isolated from the rest of the body. It is postulated that reserpine releases a humoral agent from the central nervous system that acts to stimulate the stomach.

9771 STIMULATION OF GASTRIC-ACID SECRETION BY HISTAMINE, PENTAGASTRIN, AND PENTAGASTRIN-PROPANTHELINE AFTER VAGOTOMY IN MAN. (E.) Bank, S. (Groote Schuur Hosp., Cape Town, South Africa), I. N. Marks, J. H. Louw and N. Tigler-Wybrandi. Lancet 2(7506):67-69, 1967.

Of 18 patients who had undergone vagotomy-and-drainage procedures, 15 had duodenal ulceration, 1 had a prepyloric ulcer, 1 had pyloric obstruction of undetermined origin and in the remaining patient, no ulcer was found at operation. In 13 of the patients, the vagotomy was truncal and in 5 it was selective. Augmented histamine tests, pentagastrin (6 µg/kg, inj. s.c.) tests, and propantheline (30 mg, admin. i.m.)-pentagastrin tests were performed on the patients within 7-14 days of each other at least 3 mo. after vagotomy. The mean acid output after stimulation by pentagastrin was greater than the mean acid output after max. histamine stimulation. Propantheline, an anticholinergic agent, effectively reduced the acid response to the pentagastrin after complete vagotomy. Both the increased acid output after stimulation with pentagastrin and the reduction after propantheline were largely due to changes in the vol. of secretion. These results suggest that in man the gastric parietal cells after vagotomy respond more readily to gastrin-like stimulants than to histamine.

9772 DIFFERENCE IN RESPONSES BETWEEN DOGS AND CATS TO LARGE DOSES OF GASTRIN ON GASTRIC SECRETION. (E.) Emås, S. (VA Ctr., Los Angeles, Calif.) and M. I. Grossman. Gut 8(3):267-275, 1967.

The effect of a rapid i.v. inj. of a large dose of gastrin extract (3.2 or 6.4 g/kg body wt., chiefly the former) on gastric secretion induced by a background stimulation with histamine or gastrin was compared in conscious cats and dogs equipped with gastric fistulas. In dogs, rapid gastrin inj. markedly inhibited acid secretion induced by gastrin or histamine; after truncal vagotomy, this inhibition became even more pronounced. In cats, rapid inj. against background stimulation with histamine markedly increased acid secretion, presumably by a potentiating action of histamine and gastrin. Against background stimulation with gastrin the rapid inj. increased acid secretion to preinjection levels in cats; in cats, truncal vagotomy abolished the effect of the rapid inj. on acid secretion. In spite of the marked difference between these 2 species in the effect on acid secretion, rapid gastrin inj. against background stimulation with histamine increased pepsin secretion in both species; the increase in pepsin secretion was moderate in cats and marked in dogs, and the increase remained after truncal vagotomy. Against background stimulation with gastrin, the rapid gastrin inj. did not alter pepsin secretion in dogs, but moderately increased it in cats; the same results were obtained after truncal vagotomy.

9773 EFFECT OF TRUNCAL VAGOTOMY ON ACID AND PEPSIN RESPONSES TO HISTAMINE AND GASTRIN IN CATS. (E.) Emås, S. (VA Ctr., Los Angeles, Calif.) and M. I. Grossman. Amer. J. Physiol. 213(3):657-662, 1967.

Pepsin and acid responses to graded doses of histamine and hog gastrin extract were studied before and after truncal vagotomy in cats with gastric fistulas. Before vagotomy, gastrin and histamine produced the same max. rate of acid secretion. After vagotomy the max. rates with these 2 stimulants also were equal, but approx. 30% lower than before vagotomy. The latter procedure shifted the dose-response curves to the right. Before vagotomy the highest pepsin responses to histamine were produced by doses that gave submaximal acid responses; doses that produced max. rate of acid secretion depressed pepsin secretion. The same dose of gastrin was required for max. pepsin response as for max. acid response. Max. pepsin response to gastrin was higher than to histamine. Truncal vagotomy greatly reduced the max. pepsin response to both histamine and gastrin; after vagotomy, the pepsin responses to the entire range of doses of these 2 agents never exceeded basal output before vagotomy. The reduction of the max. acid and pepsin responses by vagotomy could not be overcome by increasing the dose of histamine or gastrin. It is concluded that truncal vagotomy reduces the responsiveness of the acid- and pepsin-secreting cells to both histamine and gastrin.

9774 THE EFFECT OF VAGOTOMY ON GASTRIC SECRETION ELICITED BY PENTAGASTRIN IN MAN. A MULTICENTRE STUDY. (E.) Gillespie, I. E., V. I. McCusker, G. Gillespie, I. D. A. Johnston, J. Spivey, R. H. Allsopp, R. A. Payne, A. G. Cox, M. Vedast, G. S. Makin, S. R. Srivastava, D. Johnston, K. Jepson and H. L. Duthie. Lancet 2(7515):534-536, 1967.

The effect of proven total gastric vagotomy on gastric-acid secretion in response to i.v. gastrin pentapeptide in 54 patients (all men) was a 62% reduction in the peak acid output when a dose-rate of 6 µg/kg/hr. of pentapeptide was used; with a dose-rate of 12 µg/kg/hr., the reduction was 51%. Reduction in the max. response, irrespective of dose, was 58%. Thes results are similar to those when max. doses o histamine are given as the stimulus to gastric secretion. With both dose-rates, mild side-effects of lightheadedness and slight nausea were experienced in several patients; with the 12 µg dose-rate, 3 patients became severely nauseated and had headaches, and the test was therefore terminated. The larger dose-rate of pentagastrin (12 µg/kg/hr.) elicited secretion of more acid than the smaller (6 µg/kg/hr.) after vagotomy, but it produced less acid when the vagi were intact. This suggests that afte vagal denervation the sensitivity of the parietal cell to gastrin pentapeptide is altered.

9775 USE OF PENTAGASTRIN IN A TEST OF GASTRIC ACID SECRETION. (E.) Johnsto D. (Roy. Infirm., Sheffield, England) and K. Jepson. Lancet 2(7516):585-588, 1967.

A gastrin test is described in which 6 µg/kg of pentagastrin is inj. i.m. and the gastric secretory response followed for 30 min. Dose response studies in healthy volunteers and patients (with duodenal or gastric ulcer, hiatu hernia, pernicious anemia and gastric carcinoma showed that this dose elicited max. levels of acid secretion. The peak response correspondec to the 20-min. period between 10 and 30 min. after the inj. Peak acid output was reproducible on repeated testing. Minor side-effects (slight nausea, lower extremity weakness, light headed sensation) were recorded in 7% of the subjects. This test appears to be of equal clinical value to any in use at present, and ha clear advantages in its brevity, simplicity and lack of side-effects.

9776 COMPARISON OF ENDOGENOUS AND EXOGENOUS GASTRIN IN STIMULATION OF ACID AND PEPSIN SECRETION. (E.) Cooke, A. R. (U. California Sch. Med., Los Angeles), D. L. Nahrwold, R. M. Preshaw and M. I. Grossman. Amer. J. Physiol. 213(2):432-436, 1967.

In dogs with a transplanted antral pouch, gastric fistula and Heidenhain pouch, a graded increase in acid and pepsin response occurred from the Heidenhain pouch and gastric fistula when acetylcholine, in conc. ranging from 15 µg/ml to 1000 µg/ml, was perfused through the antral pouch. Max. acid output occurred with conc. of acetylcholine at or above 1,000 µg/ml. The max. acid output from the gastric fistula was equal in response to endogenous gastrin and to exogenous hog gastrin; the max. acid output from the Heidenhain pouch was smaller in respons to endogenous gastrin than to exogenous hog gastrin. Max. pepsin output with endogenous or

enous gastrin stimulation was greater than
histamine. These results show that dose-
onse relations for acid and pepsin secretion
similar with endogenous gastrin and exogenous
gastrin in all principal features.

7 INHIBITION OF GASTRIC ACID SECRETION
BY A PURIFIED BACTERIAL LIPOPOLY-
HARIDE. (E.) Baume, P. E. (Roy. North
e Hosp., Sydney, Australia), A. Nicholls and
. Baxter. Nature (London) 215(5096):59-60,
.

rified lipopolysaccharide, prepared from the
ne-dependent mutant Escherichia coli ATCC
8, was inj. i.v. to Sprague-Dawley rats in
easing conc. (1-4,000 μg/kg), and the secre-
of gastric acid by these animals was meas-
by pylorus ligature. The purified E. coli
polysaccharide was a powerful inhibitor of
gastric acid secretion. Acid secretion was
st abolished by all doses greater than 50
g, while secretion was reduced to 50% of
trol values by a dose of 1.25 μg/kg. Larger
es (1000; 2000; and 4000 μg/kg) of the lipo-
saccharide were toxic. The reduced total
tric blood flow after inj. of lipopolysaccharide
associated with reduced gastric mucosal blood
, which was the cause of reduced secretion
acid. This effect on total gastric blood
appeared to be mediated by a separate sub-
nce produced in the body, probably in the
estine, since it could not be produced by
opolysaccharide inj. directly into the gastric
sels (previously reported). Lipopolysaccharide
ears to be 1 of the most potent of all
ibitors of acid secretion yet described.

8 GASTRIC SECRETION IN UNANESTHETIZED
CHICKENS. (E.) Long, J. F. (Albany
. Coll., N. Y.). Amer. J. Physiol. 212(6):
3-1307, 1967.

unanesthetized, fasting, cannulated White
horn chickens weighing 1-2 kg, basal gastric
retory vol. was measured at 15-min. intervals
to 6 hr., beginning after 30-45 min. gastric
inage to rid the crop and gizzard of residual
tent. The mean value obtained was 15.4 ml/hr.;
mean acid conc. was 93 mEq/liter; the mean
sin conc. was 247 PU/ml. Comparable tabula-
ns after s.c. admin. of histamine acid phos-
ate (4 mg/kg, single dose) were 38.8 ml/hr.,
5 mEq/liter and 210 PU/ml, resp. Admin. of
sulin (4 or 8 U/kg, i.v., single dose), reduced
stric acid conc. by 30-50% and by more than
%, resp., with a corresponding inhibition of
stric secretory vol. The degree of diminution
s directly dose-related, rather than related to
degree of hypoglycemia induced. There was
consistently significant pattern of change,
concerned pepsin secretion. Following atropine
mg/kg, i.v., single dose), the basal secre-
ry rate dropped to zero within 20 min., re-
ined there for 45 additional min., returned to
normal within 90 min. after inj. In chickens bearing both gastric and intestinal fistulas intraduodenal infusion of 6 ml triole n over a 15-min. period exerted no significant effect on either acid or pepsin secretion during a 2-hr. observation period following. It is concluded that the chicken secretes considerably more gastric acid and pepsin, both in the basal state and following histamine stimulation, than does man, the dog, the rat or the monkey, and may therefore be of value in experimental studies of gastric secretory inhibitors.

9779 INHIBITORY EFFECT OF FATS ON GASTRIC SECRETION. (Rus.) Gzgzian, D. M. (Sechenov Inst. Evolutionary Physiol. & Biochem., Leningrad, USSR) and M. G. Zaks. Fiziol. Zh. SSSR Sechenov 53(6):711-716, 1967.

The amount of gastric juice in the first hr. of stimulation with meat, or fat (oil) + meat, or alcohol (8%; 15 min. before meat) + fat + meat was, in the dog with Pavlov's stomach (1), 38.7, or 11.8, or 30.9 ml, resp. In the dog with Pavlov stomach and partial gastric sympathectomy (removal of both abdominal sympathetic chains) (2) it was 2.1, or 4.9, or 4.7 ml, resp.; and in the dog with Heidenhain stomach, partial gastric sympathectomy and resection of all visible nerves of the gastric vascular branch (3) gave 8.0, or 1.2, or 17.4, resp. Three-hr. experimentation in dog 1 showed that with stimulation by meat or alcohol + fat + meat the highest secretion was found in the first hr., while with stimulation with fat + meat the max. secretion occurred in the second hr. Av. acidity, studied in Dog 3, in first hr. of the experiment was with stimulation with meat 0.41/0.47, with fat + meat 0.23/0.36, with alcohol + fat + meat 0.50/0.54; digesting power of the juice showed no essential differences. Antidiuretic effect of fat (sunflower or butter) was studied in 2 dogs with exposed ureters by Pavlov-Tsltovich and gastric fistula by Basov. Av. diuresis before fat admin. of 3.2 ml/min. decreases after admin. of fat to 0.52 ml/min. (or by 83%). Antidiuretic reaction started 13 min. after and reached its max. 72 min. after admin. of fat; such reaction lasts about same time as the inhibitory effect of the same dose of fat on gastric secretion on meat. Antidiuretic action of fat is specific. Antidiuretic effect of fat, which was given after alcohol, was significantly lower than at pure fat antidiuresis; when alcohol was given on already developed fatty antidiuresis, a fast inhibition of antidiuretic reaction was noted and diuresis increased above the initial level. Therefore, the inhibition of gastric juice secretion by fat was completely eliminated by preliminary admin. of alcohol; marked antidiuretic effect, induced by fat feeding on the basis of water diuresis, is also eliminated by admin. of alcohol. Based on the data obtained it is suggested that hormones of the posterior lobe of the pituitary participate in the mechanism of inhibition of gastric secretion.

9780 INTRAGASTRIC PRESSURE AS A FACTOR INFLUENCING REDISTRIBUTION OF PEPSINOGEN AND CHLORIDES SECRETED IN THE GASTRIC JUICE AND URINE.

(Rus.) Korot'ko, G. F. (Kalinin State Med. Inst., Andizhan, USSR) and A. M. Musaev. Biull. Eksp. Biol. Med. 63(5):17-22, 1967.

Seven dogs with isolated stomachs of large vol. (by Pavlov, Savich, and Ugolev methods) and exposed ureter (by Pavlov) were studied. Increase of intragastric pressure up to 10-15 mm Hg resulted in a decrease of pepsinogen excretion in the secretion composition/time U, which became more pronounced with time and occurred due to a decrease in secretion and pepsinogen content in the juice. In some experiments only in the first hr. of increased intragastric pressure was there secretion with a low free acid content. With a decrease in proenzyme secretion in the juice, regular increases in uropepsinogen excretion occurred; this process increased urinary pepsinogen content. At a pressure of 30 mm pepsinogen exosecretion markedly increased up to 3-4 hr. and toward 6-8 hr. decreased and reached lower values than that obtained at atmospheric pressure in the gastric cavity. The increase of exosecretion is due to an increase of proenzyme content in secretion and to an increase of secretion vol. The pepsinogen exosecretion increase was accompanied by a decrease of uropepsinogen in consequence to a decrease in diuresis and proenzyme content in the urine. A pressure of 20 mm increases pepsinogen exosecretion to a lesser degree than a pressure of 30 mm. A pressure of 40 mm always depresses excretion of pepsinogen in the gastric juice. A reverse correlation was found between exosecretion and increase of pepsinogen depending on the degree of intragastric pressure. Negative pressure (20-40 mm) increased the conc. and excretion of chlorides in the juice but had no effect on the synthesis of acid. Increase of chloride excretion in the juice was accompanied by a decrease of their renal excretion. A depression of chloride excretion using the exosecretory route (at positive pressure, 10-15 mm) caused an increase of their excretion in the urine.

9781 CLINICAL STUDY OF THE SUPPOSED "SPARING EFFECT" ON HYDROCHLORIC ACID SECRETION ATTRIBUTED TO ACIDIFIED MILK.

(It.) Cantele, M. P. (Carlo Erba Ther. Res. Inst., Milan, Italy) and F. Brughera. Gazz. Sanit. 38(1-2):37-41, 1967.

The effects of various types of milk on gastric acid secretion were studied in 10 normal infants (2-4 wk. old). Group 1 (5 infants) were fed Milk No. 1 (powdered 50% cream cow's milk containing 20% protein, 11.5% lipids, 62.5% sugar, and 4% mineral salts) on day 1 and Milk No. 2 (same as above plus 3.22% lactic acid; pH approx. 4.8) on day 2. Group 2 (5 infants) were fed Milk No. 1 on day 1, Milk No. 2 on day 2, and human milk on day 3. Infants were fasted for 7-8 hr. before receiving 100 ml of each type of milk. Thirty min. after feeding, a gastric tube was inserted and 2-ml samples of gastric juice were obtained at 30, 60, 120, and 180 mi
Determination of pH and titration of Cl conten
were performed for each sample. No difference
was observed in gastric Cl values after feedin
with Milk No. 1 or Milk No. 2 in each group,
while gastric Cl values were perceptibly inferi
in infants fed human milk. No conclusions can
be drawn from these findings since the Cl content of human milk was lower than that of cow's
milk (32 mg/100 ml and 105 mg/100 ml, resp.),
and it is not possible to determine if the lowe
gastric Cl values were due to a "sparing effect
or to lower Cl content of the milk itself. The
av. pH gradient of the gastric juice was higher
(0.70-0.84 pH U) in infants fed Milk No. 1 tha
in those fed Milk No. 2 (0.3 pH U), but was highest (1.4 pH U) in infants fed human milk. Contrary to what has been hitherto believed, i
seems doubtful from the present findings that acidified cow's milk has a "sparing effect" on gastric acid secretion.

9782 VARIOUS ASPECTS OF GASTRIC SECRETION IN RATS TREATED BY THE SHAY METHOD.

(It.) Vecchioni, R. (U. Padua, Italy), G. Perr
and C. Cordiano. Acta Chir. Ital. 22(6): 693-703, 1966.

Various parameters of gastric secretion (as wel
as blood glucose levels) were investigated in male albino rats (Italicus strain; av. wt. 300
subjected to pyloric ligation according to the Shay method with or without subsequent i.v. inj
of 0.5 U/kg of insulin. Animals were sacrifice
15, 30, 45, 60, 90, 120, 150, 180, and 240 min. after surgery, and gastric juice (after centrifugation at 1500 rpm for 15 min.) and blood wer
collected for the necessary tests. The vol. of gastric secretion showed a gradual increase ove
the 4-hr. period in untreated rats, while insulin-treated rats showed a significant incre
within the first 2 hr. Total acid content of the gastric juice (determined by the Introzzi method) rose within the first 2 hr. from 50 to 99 mEq/liter and then decreased moderately between hr. 2 and 4; insulin increased the tota
acid content markedly (approx. 120 mEq/liter within the first hr.). The pH of gastric juice (electrometric method) decreased from 2.1 at 15 min. to 1.5 at 4 hr. in untreated animals; insulin produced a more marked drop (1 U within the first hr.). No significant differences wer
observed between the 2 groups with regard to electrolyte content of the gastric juice, as determined by flame photometry. Pepsin conc. (Mett method) was highest (above 160 Mett U) within the first hr. and stabilized at 150 Mett U between hr. 3-4; pepsin levels in insulin-treated rats reached 190 Mett U within the firs
45 min. Mucin (glucuronic acid) conc. (Siplet method) dropped from 14 mg/100 ml at 15 min. to 6.2 mg/100 ml at 2 hr. and increased again between 2 and 4 hr.; results were the same in insulin-treated rats.

VARIOUS "EARLY" RESULTS OF BILATERAL TRUNCAL VAGOTOMY. (EXPERIMENTAL STUDY).

Vecchioni, R. (U. Padua, Italy), C.
ano and G. Perrino. Acta Chir. Ital. 22(6):
10, 1966.

albino rats (Italicus strain; av. wt. 300 g)
subjected to bilateral truncal vagotomy
ved by pyloric ligation immediately after-
, 12 hr., 48 hr., 6, 8, or 15 days after
omy. Animals were sacrificed 5 hr. after
ion, and gastric juice and blood were
cted for the determination of various para-
s. Controls were subjected to pyloric
ion alone (Group 1) or to gastric fistula
ion (Group 2). A 5% mortality occurred
vagotomized rats and substitution was made
new animals. The vol., pH, total acid con-
and pepsin conc. of the gastric juice was
er in controls of Group 1 than in those of
2; electrolyte and mucin levels of the
c juice, as well as blood parameters, were
ar in both control groups. Vagotomy and
c ligation decreased the vol. and total
content of the gastric juice but increased
ues as compared to Group 1 controls. No
ences were observed with regard to gastric
or blood electrolyte levels. Gastric juice
nd pepsin conc. decreased progressively as
terval between vagotomy and pyloric liga-
ncreased; pH and total acid values showed
nhibition at 6- and 8-day intervals.
content was lowest in animals with a 6-day
al and close to normal in animals with a
interval. Total blood proteins showed a
decrease in animals with a 6-, 8-, or 15-
terval between vagotomy and pyloric
on. Other blood parameters (nonprotein
en, glucose, hematocrit, electrolytes)
no differences among the various groups.

POSSIBILITY AND RESULTS OF SELECTIVE GASTRIC VAGOTOMY IN THE RAT. (It.)

oni, R. (U. Padua), O. Fontanin, C. Cordiano
Perrino. Acta Chir. Ital. 22(6):729-735,

ive gastric vagotomy was performed in male
rats (Italicus strain; av. wt. 300 g) and
ed by pyloric ligation 6 days later.
c juice was collected and various para-
determined. Controls were subjected to
laparotomy to expose the stomach (Group 1)
bilateral truncal vagotomy (Group 2). To
all the animals subjected to selective
c vagotomy survived and no invalidating
were observed as of 5 mo. following
y. Results were similar to those observed
s of control Group 2. The vol., total
ontent, pH, and pepsin conc. of the gastric
of animals subjected to selective gastric
my was 1.12 ml/100 g, 36 mEq/liter, 3.84,
Mett U, resp.; similar values in Group 2
ls were 1.08 ml/100 g, 38 mEq/liter, 3.92,
Mett U, resp. Results indicate that this
vely simple method gives results comparable
in every way to those observed in rats treated by bilateral truncal vagotomy. The operation is well tolerated, and if the surgeon's movements are careful, asepsis maintained, and proper alimentation admin. in the postoperative period, there will be no deaths.

9785 QUALITATIVE COMPOSITION OF GASTRIC JUICE AND TEMPERATURE OF GASTRIC MUCOUS MEMBRANE.

(Uk.) Zagorodneva, A. G. (Inst. Physiol., Acad. Med., Kiev, USSR). Fiziol. Zh. (Kiev) 13(1):114-118, 1967.

Dogs with gastric fistulas (3) and stimulation of gastric secretion by histamine (0.4 ml of 0.1% soln., s.c.) comprised Group 1, dogs with isolated denervated and innervated pyloric part of stomach with fistula and anastomoses between stomach and duodenum (3) and gastric stimulation by peptone (5% soln. into pylorus) comprised Group 2, and dogs with additional admin. of 0.25% soln. of HCl into the pylorus made up Group 3. Study of these showed that isolation of large quantities of gastric juice with high acidity is accompanied by an increase in the temperature of the mucous membrane. With a decrease in juice acidity and a secretion intensity, a decrease occurred in the temperature of the mucous membrane. At the time of isolation of juice with high protein conc., mucous membrane temperature decreased, while with increased temperature of gastric mucous membrane, juice with low conc. of proteins occurred. At decreased or increased temperature, total acidity (in %) was: In Group 1 - 0.36 or 0.49, resp., in Group 2 - 0.35 or 0.45, resp., and in Group 3 - 0.17 or 0.45, resp. Total protein amount (mg) was: In Group 1 - 18.0 or 12.7, resp., in Group 2 - 11.8 or 10.4, resp., and in Group 3 - 11.2 or 6.1, resp.; Juice vol. (ml) was: In Group 1 - 10.3 or 8.8, resp., in Group 2 - 6.0 or 8.7, resp., and in Group 3 - 3.4 or 15.4, resp. A positive relationship exists between the changes in the temperature of gastric mucous membrane and qualitative composition of isolated gastric juice.

9786 A COMPLEX STUDY OF THE EFFECT OF LASTING NOCICEPTIVE (PAINFUL) STIMULATION ON THE SECRETORY AND EVACUATORY GASTRIC FUNCTION.

(Rus.) Grechishkina, A. P. (Lugansk Med. Inst., USSR) and V. Iu. Zhabenko. Fiziol. Zh. SSSR Sechenov 53(6):699-704, 1967.

Study was made on 10 dogs with Pavlov pouch (4) or Pavlov's pouch with fistula of the fundal part in which gastric secretion was stimulated by ground meat mixed with $BaSO_4$ and H_2O. Chronic nociceptive stimulation was provoked by stimulation of the posterior radicles of the lumbar section of the spinal cord by ligature with sharp beads, after laminectomy (Kravtsov's method); or by prolonged (2 or 5 hr.) periodically measured nociceptive stimulation of the sciatic nerve by electric current. In dogs treated by

Kravtsov's method, 2 wk. later there was a decrease of total amount of gastric juice, mostly because of reduced secretion during the first hr. as compared to controls; simultaneously the time of evacuation of the gastric content was increased. The changes of secretory and evacuatory gastric function were observed during 3-4 wk., which thereafter, was restored to the initial level. In a dog with laminectomy alone both functions were only slightly changed, e.g., the former was reduced, the latter delayed, for 1 wk. after surgery. Under the action of prolonged nociceptive stimulation the changes in gastric secretion had a biphasic character, e.g., an inhibition of gastric secretion during stimulation, and an increase of gastric secretion after discontinuation of stimulation. At the same time a marked suppression of evacuation of the gastric content was found.

9787 HYPOTHALAMIC STIMULATION AND GASTRIC SECRETION IN THE DOG.

(E.) Mason, G. R. (Stanford U. Sch. Med., Palo Alto, Calif.) and T. S. Nelsen. Amer. J. Physiol. 213(1): 21-24, 1967.

Hypothalamic stimulation has been associated with variable results when gastric secretion was the observed response; this variation has been due to inadvertent lesion creation from unbalanced wave-forms, incomplete sampling of secretion parameters, and limited stimulus control. Monopolar electrodes were implanted in the hypothalamus of each of 19 dogs (13 mongrels, 6 beagles); 6 dogs were used to prepare isolated innervated (Pavlov) gastric pouches. Electric hypothalamic stimulation of unanesthetized dogs was done for periods of up to 6 hr. In general, a current of less than 1 milliampere was used for stimulation; the stimulus was a continuous train of biphasic square waves, balanced for net current flow of 0, at frequencies of 10 and 100 cycles/sec. There was a consistent increase in both vol. and conc. of gastric acid from innervated gastric pouches after anterior hypothalamic stimulation at 10 cycles/sec.; the vol. and free acid rose together 15-30 min. after onset of stimulation. The secretion was relatively mucus-free, reaching conc. of 130 mEq/liter HCl. The insulin-hypoglycemic vagal stimulation of gastric secretion was used as a standard of comparison for electric hypothalamic stimulation. The responses were similar in time of onset and simultaneous rise of vol. and free acid conc. Hypoglycemia did not occur after electric stimulation alone.

9788 GASTRIC SECRETORY RESPONSE TO AMYGDALOID OR HYPOTHALAMIC STIMULATION IN MONKEYS.

(E.) Smith, G. P. (U. Pennsylvania Sch. Med., Philadelphia) and P. R. McHugh. Amer. J. Physiol. 213(3):640-644, 1967.

Electrical stimulation of the amygdala or hypothalamus produced defense reactions, marked increases of plasma 17-hydroxycorticosteroids
and significant inhibition of gastric acid
outputs in conscious macaque (*Macaca mulatta*)
monkeys equipped with gastric fistulas. Pepsi
outputs decreased less during brain stimulatic
In the 4 hr. after central stimulation, gastri
acid output did not increase significantly
above prestimulation values in spite of increa
plasma 17-hydroxycorticosteroids. These findings are evidence for including increases of
plasma 17-hydroxycorticosteroids and decrease
of gastric acid output as visceral components
of the defense reaction in conscious macaque
monkeys. Under the conditions of these
experiments, there was no evidence for an
adrenal phase of gastric acid stimulation.

9789 KINETICS OF GASTRIC JUICE SECRETION: A CORRELATION OF ARTERIOVENOUS DIFFE ENCES WITH THE COMPOSITION OF THE GASTRIC JUI

(E.) McQuarrie, D. G. (Minneapolis VA Hosp.,
Minn.), A. Eichenholz, A. S. Blumentals and
J. A. Vennes. Surgery 62(3):475-486, 1967.

Blood gas and electrolyte changes were simultaneously measured before and after a max.
betazole (150 mg, admin. i.v.) secretory
stimulus in the intact dog stomach; these cha
were related to the vol. and composition of t
gastric juice evolved. At baseline, the mean
gastric juice vol. was scanty (11.2 ml/hr.) a
had a low H ion conc.; in response to betazol
stimulation, there was a 9-fold increase in
gastric juice vol. with 4-5 times increase in
ion conc. In the unstimulated stomach, the
gastric venous blood showed O_2 consumption, a
rise in pCO_2 and a lower pH, when compared to
arterial blood; with vigorous gastric secreti
there was a marked change with an increased O
consumption, a venous pCO_2 below that of the
arterial pCO_2 and a rise in the venous pH. A
marked increase of bicarbonate conc. in gastr
venous blood was indicative of net extraction
H ion from blood perfusing the stomach. In
conjunction with the 9-fold increase in gastr
juice vol. in response to betazole, there was
increase in the gastric venous osmolality;
gastric juice osmolality was not significantl
below that of arterial blood. With stimulati
of gastric secretion there was a net extracti
of Cl across the vascular bed; the venous-arterial difference of Na and K was increased
and electrical neutrality was preserved by th
concomitant rise in bicarbonate conc. There
no significant relative change in blood flow
the left gastric artery in response to betazo
In the stimulated dog stomach the amount of f
CO_2 removed from plasma and the CO_2 produced
endogenous gastric metabolism did not quantit
tively account for the increased bicarbonate
conc. in the gastric venous blood when correc
for hemoglobin desaturation and lactate-pyruv
production; the most reasonable source of
additional CO_2 in the intact animal was bicar
containing secretions which reacted with H io
in a dilution-secretion, liberating freely

sible CO_2. Data of gastric blood flow
ed from osmolality in conjunction with the
ive change in the left gastric blood flow
sted that the response to betazole pro-
some redistribution of flow within the dog
ch.

TRANSMURAL POTENTIAL AND STIMULATED
ACID IN INNERVATED RAT STOMACH PER-
AT pH 3.0. (E.) Vaughan, B. E. (US Naval
. Defense Lab., San Francisco, Calif.),
Ridley and J. T. Cummins. Amer. J. Physiol.
:651-656, 1967.

as secreted at high rates, reaching 5-13
/min., promptly after s.c. inj. of 400 µg
emipurified gastrin preparation using
nesthetized with pentobarbital and pre-
for a recirculation perfusion of the
c lumen. The influent catheter entered
h longitudinal incision of the esophageal
and the effluent catheter through the
s. Only the inner epithelial tube of the
gus was ligated to the entry catheter.
ation of the "pH-stat" principle showed
timulated acid secretion was sharply cut
en the perfusion medium was changed rapidly
H 2.5 to pH 2.1. Sectioning of the vagal
and their associated fibers in the fore-
h area caused an immediate inhibition of
ated acid secretion; this could not be
ed by gastrin re-inj. Potential differ-
usually decreased from 41 to 36 millivolts
n resting and stimulated acid rates, but
as not an invariable finding. Short-
t current and conductance doubled under
conditions. Atropine, at doses sufficient
ck all receptor sites for inhibition of
c potential, had no effect on the stimula-
f acid secretion by re-inj. of gastrin.

EFFECT OF PROXIMAL DUODENAL ACIDIFICA-
TION UPON GASTRIC SECRETION IN THE
AT. (E.) Lee, Y. H. (UCLA Sch. Med., Los
s, Calif.) and J. H. Thompson. Amer. J.
is. 12(8):795-803, 1967.

fects of proximal duodenal acidification
asal unstimulated (spontaneous), max.
ine-stimulated and max. insulin-stimulated
c-acid- and electrolyte secretion in the
ylorus-ligated male Sprague-Dawley rat
0 g) were studied. Rats were given s.c.
saline (2.0 ml/kg), histamine phosphate
kg) or crystalline Zn insulin (40 U/kg),
e then divided into 9 groups: 3 received
usion, 3 were perfused with 0.9% normal
and 3 were perfused with 0.05 N HCl. The
on unstimulated basal gastric secretion
that gastric juice vol. in the saline-
d group (3.1±0.3 ml/2 hr.) was slightly
than the vol. collected from rats in the
group (2.5±0.2 ml/2 hr.); the low gas-
cretory vol. produced in rats perfused
05 N HCl (1.6±0.1 mg/2 hr.) was
statistically different from control and normal saline-perfused rats. Similarly, with gastric juice vol./100 g rat body wt., total acidity and acid output, comparable values were found in control rats (nonperfused) and in saline-perfused animals, with no significant difference between them; significantly lower values in all of these parameters were found in the acid-perfused animals. Values for Na ion in the control (nonperfused group), normal saline-perfused and acid-perfused groups were, resp., 71±4, 66±4 and 92±6 mEq/liter; for K ion, these values were 13.5±1.1, 15.6±0.7 and 6.7±0.7 mEq/liter, resp., and for Cl ion they were 105.5±3.5, 109.3±2.8 and 87.4±3.9 mEq/liter, resp. The differences between acid-perfused rats and the values for the other 2 groups were statistically significant. Duodenal acidification was without effect on any parameters of gastric secretion stimulated by a max. dose of crystalline Zn insulin or histamine phosphate.

9792 CAPILLARY PERMEABILITY AND TISSUE EXCHANGE OF WATER AND ELECTROLYTES IN THE STOMACH. (E.) Alvarez, O. A. (U. Chile, Santiago) and D. L. Yudilevich. Amer. J. Physiol. 213(2):315-322, 1967.

First-passage tracer dilution curves of siderophilin-^{59}Fe (intravascular reference), tritiated water, ^{22}Na, ^{36}Rb and ^{36}Cl were obtained after an intra-arterial inj. in an *in situ* chambered gastric wall preparation in the dog. Tracer fractional extraction and interstitium-blood turnover rates were computed. The data were interpreted in relation with the presence of 2 nutritional capillary beds in the gastric wall: smooth muscle and mucosa. Extractions in smooth muscle for Na, Cl, Rb and tritiated water av. 0.56, 0.72, 0.74 and 0.85, resp.; in mucosa, they av. 0.82, 0.86, 0.91 and 0.89, resp. Capillary permeability-surface product ratios ^{22}Na/tritiated water decreased with increasing blood flow reaching a relatively constant value below the free-diffusion constant ratio. This was interpreted as showing both substances do not cross the capillary barrier by simple diffusion through the same area. Back diffusion to blood of ^{86}Rb was reduced in the secreting state, with a simultaneous increase in its specific activity in the gastric secretion. It is suggested that Rb passes from blood to gastric secretion only through mucosal cells.

9793 THE EFFECT OF ARTERIAL pCO_2 ON GASTRIC MUCOSAL BLOOD FLOW MEASURED BY CLEARANCE OF Kr^{85}. (E.) Bell, P. R. F. (Western Infirm., Glasgow, Scotland) and A. C. Battersby. Surgery 62(3):468-474, 1967.

Gastric mucosal blood flow was measured by estimating the mucosal clearance of ^{85}Kr in order to investigate the effect of changes in arterial pCO_2; the problem of arteriovenous shunts was overcome by measuring the mucosal flow alone. Hypercapnia was induced in dogs by addition of CO_2 to inspired gases, commencing at 1% and ending at 12%; significant increases in flow were noted. In each animal, this increase in flow was max. at an arterial pCO_2 of 95-100 mm Hg. Hypocapnia was induced in dogs by progressively increasing the ventilatory vol.; hypocapnia caused significant reduction in mucosal flow with progressive reduction in arterial pCO_2. Four additional experiments were done to ensure that the changes in flow were not due to alterations in arterial pH; in 2 a metabolic alkalosis was progressively induced by admin. of 8.4% $NaHCO_3$, and in the remaining 2 a metabolic acidosis was induced by infusion of 2% lactic acid, the pCO_2 on each occasion being maintained within narrow limits by altering ventilatory vol. No significant change in flow occurred over a wide range of pH values with relatively constant pCO_2 (45±6 mm Hg), suggesting that the changes observed with changes in pCO_2 were not due to alteration in pH. It is suggested that pCO_2 should be monitored and maintained within narrow limits when estimates of gastric blood flow are being made under general anesthesia.

9794 HISTOCHEMICAL STUDY OF THE MUCOSUBSTANCES IN THE CANINE STOMACH. I. THE RESTING MUCOSA.

(E.) Gerard, A. (New York Med. Coll., N. Y.), R. Lev and G. B. J. Glass. Amer. J. Dig. Dis. 12(9):891-912, 1967.

Using histochemical and autoradiographic ($^{35}SO_4$) technics, 2 sulfated compounds of epithelial origin were identified in dog (17, mongrel) gastric (fundus and antrum) mucosa. One was a sulfated glycoprotein, produced by the surface epithelium, and the other a chondroitin sulfate A- or C-like material found in chief cells and pyloric glands; both glycoprotein and acid mucopolysaccharide probably contributed to the sulfated fractions found chemically in dog gastric juice. A sialidase-susceptible mucin was found predominantly within superficial cells of the antrum and fundus; this may be the source of the sialic acid found in the gastric secretions. A strictly neutral glycoprotein was found in the mucous neck and parietal cells, possibly indicating a relationship between these 2 cellular elements. In cells containing neutral and acidic mucins, the vicinal hydroxyl and anionic groups were judged to be in close proximity. Strong staining for basic protein was found in parietal cells and a less intense reaction in surface epithelium. S-containing amino acids were identified by direct and indirect technics in surface epithelium.

9795 ROLE OF INHIBITION OF GASTRIC MUCOUS SECRETION IN THE PHENOMENON OF GASTRIC MUCOSAL INJURY BY INDOMETHACIN.

(E.) Menguy, R. (U. Chicago, Ill.) and L. Desbaillets. Amer. J. Dig. Dis. 12(9):862-866, 1967.

Vagally denervated gastric-antral pouches de
void of acid-secreting mucosa were construct
in 5 dogs, who received 5 mg/kg of indometha
day for a 10-18 day test period. Three dogs
died suddenly after 10, 13 and 18 days, resp
of admin. of indomethacin; these all had
duodenal ulcers, 2 of which were perforated,
1 dog also had a large gastric ulcer. In al
dogs the rate of secretion of gastric mucus
decreased during admin. of the drug; this
decrease ranged from 21-36% of control value
The output of nondialyzable mucosubstance
decreased in all but 1 of the dogs, as did t
conc. of sialic acid. In 3 of the dogs the
conc. of L-fucose in mucosubstance was decre
there was no apparent relation between the
changes in the conc. of these 2 sugars, exce
in 1 dog, in which the least change in sial
conc. was accompanied by the largest decrea
in the conc. of L-fucose. The conc. of
hexosamines decreased in 3 dogs; neutral su
remained unchanged. In all dogs, the carbohydrate:protein
ratio dropped during the te
period. In the 2 surviving animals, the ra
of mucus secretion returned to control leve
during the period of recovery from the effe
of indomethacin; however, other values retu
more slowly and the av. remained depressed
comparison with control figures. These res
suggest that gastric mucosal injury by indo
methacin may be due to altered mucosal defe
mechanisms.

9796 ACTIVE TRANSPORT OF IONS BY THE GASTRIC MUCOSA OF THE RABBIT FOETU

(E.) Kendall, A. (Bedford Coll., London) a
G. H. Wright. J. Physiol. (London) 190(3):
531-540, 1967.

The short-circuit current and absolute flux
Na and Cl ions across the gastric mucosa of
28-day rabbit fetus were measured in vitro.
substitution of Na ion in the soln. bathing
mucosal surface by choline ion or K ion res
in a 70% decrease in short-circuit current
was reversed when Na ion was restored to th
mucosal soln. The portion of the short-ci
current dependent on the presence of Na ion
the mucosal soln. was found to be equivale
the net flux of Na ion from mucosa to sero
Net flux of Cl ion from serosa to mucosa w
compared with the short-circuit current wh
persisted when Na had been replaced in the
mucosal soln. The av. results from 16 exp
ments indicated that the net flux of Cl io
equivalent to 166% of the Na ion independe
short-circuit current. These findings sug
that the component of the short-circuit cu
associated with acid secretion was indepen
of the presence of Na ion in the mucosal s
The small scale of the experiments and the
secretion of mucus by the preparation did
allow simultaneous measurement of H ion se
tion and short-circuit current. Replaceme
Cl ion by sulfate ion or glucuronate in th
soln. on both sides did not result in a re

r decrease in the magnitude of the Na ion
ndependent short-circuit current, even after
llowing time for the tissue to become depleted
f Cl ion. It is hypothesized that a nonspecific
ctive anion transport was occurring.

797 ACCELERATED MOBILIZATION AND FORMATION
OF HISTAMINE IN THE GASTRIC MUCOSA
/OKED BY VAGAL EXCITATION. (E.) Kahlson, G.
J. Lund, Sweden), E. Rosengren and R. Thunberg.
Physiol. (London) 190(3):455-463, 1967.

nanges in the rate of histamine formation and
n the histamine content of the parietal-cell-
ontaining region of the gastric mucosa were
tudied in female Sprague-Dawley rats under the
nfluence of agents that evoke or abolish vagal
citation. The hypoglycemia-producing agents,
nsulin (5 I.U., admin. s.c.) and 2-deoxyglucose
00 mg/kg, admin. s.c.), raised the mucosal
stamine-forming capacity in a manner similar
that previously observed on refeeding, gas-
rin (10 μg/kg) inj. and distention of the wall
the stomach. In cats, insulin inj. elicited
elevation of mucosal histamine-forming
pacity similar to the corresponding effect of
nsulin in rats. Hoechst 9980 (piperidino-ethyl-
phenylacetamide, 0.1 mg/kg), which inhibits
ostganglionic cholinergic transmission, counter-
cted the elevation of mucosal histamine-forming
pacity after vagal excitation, but did not
hibit changes produced by gastrin, thereby
dicating the absence of a cholinergic inter-
diary link between gastrin and changes in
cosal histamine. It is emphasized that al-
ough vagus excitation, refeeding, gastrin and
stention all produced similar changes in
cosal histamine, the clarification of the pre-
se role of histamine as a natural stimulant
r the parietal cells may necessitate a different
nd of approach.

98 A COMPARISON OF TWO METHODS OF MEASURE-
MENT OF GASTRIC EMPTYING TIME. (E.)
ernish, S. M. (Indiana U. Sch. Med., Indiana-
lis), E. B. Young, B. D. Rosenak and C. E.
dman. Amer. J. Dig. Dis. 12(8):761-774, 1967.

o methods were used to determine the rate of
stric emptying time in 5 male subjects (47-67
. old). The test meal method was more diffi-
lt to perform, requiring positioning of the
tient, installation of a gastric tube, admin.
a test meal, removal of remaining meal from
e stomach at termination of a specified period
time, washing and redraining of the stomach,
alysis of aliquots from measured specimens and
alysis of each dialysate for content of a dye
dicator. The KI saliva test required only
min. of a known quantity of KI with a standard
al and determination of appearance time of
dide in the saliva using a starch indicator
ln. These tests were used to determine the
fects of 2 drugs, atropine (1 and 2 mg) and
teronium bromide (3.2 and 6.4 mg), on gastric
emptying and secretion. Both methods provided closely correlated relative potency values for both of the drugs. The test meal method showed that when admin. p.o. heteronium bromide had a significantly greater effect on gastric secretion than did atropine. This suggests that it may be possible to separate the effects of anticholinergic drugs on motility from the effects on secretion. When compared to atropine, heteronium bromide had a greater effect on gastric secretion than on gastric emptying; 1 mg of atropine was approx. equivalent to 4.2 mg of heteronium bromide, insofar as effect on gastric emptying was concerned. Thus, a dose of heteronium bromide which is equivalent to a given dose of atropine would exert a much greater effect on gastric secretion than would that dose of atropine. The doses of both drugs used in this study did not produce any unusual or excessive untoward reactions. It is suggested that, since clinical methods for screening drugs must be simple, rapid and reliable, the KI saliva test is preferable to the test meal method for this purpose.

9799 GASTRIC HYPERSECRETION FOLLOWING MASSIVE SMALL-BOWEL RESECTION IN MAN. (E.) Aber, G. M. (Queen Elizabeth Hosp., Birmingham, England), F. Ashton, M. H. B. Carmalt and T. P. Whitehead. Amer. J. Dig. Dis. 12(8):785-794, 1967.

A case report is presented of a 54-yr.-old man who had a massive intestinal resection for multiple arterial occlusion of the mesenteric vessels; most of the patient's jejunum, and all of his ileum, cecum and proximal colon were resected. After these operative procedures, the patient required repeated gastric aspiration and was shown to have gastric hypersecretion with a daily vol. of 2-4 liters, containing 200-500 mEq of H ion. This hypersecretion resulted in gross biochemical abnormalities which, along with their phase of correction, were studied in detail. After the second resection, Na, K, Cl and H ion conc. were remarkably constant in the gastric aspirate, being approx. 34, 8, 146 and 101 mEq/liter, resp. By the seventh postoperative day, the patient had a negative Cl balance of 389 mEq, Na retention amounting to 606 mEq and a negative K balance of 52 mEq, which had been reduced from a negative level of 249 mEq on the second postoperative day. From the time of the second resection to the seventh postoperative day, the serum Cl decreased from 98 to 84 mEq/liter, the serum K fell from 4.7 to 2.9 mEq/liter and serum Na rose from 132 to 144 mEq/liter. There was a progressive rise in standard bicarbonate from 24 mEq/liter on the day of the second operation to 41 mEq/liter by the seventh postoperative day. From the fourth to the seventh postoperative days, daily gastric losses of H ion were found to be between 200 and 500 mEq, while urinary excretion of net H ion varied between 50 and 100 mEq/day. The acid-base state of the patient was corrected by i.v. infusion of 666 mEq of ammonium chloride over the seventh to ninth postoperative days. Losses of H ion in gastric aspirate and in urine exceeded 400 mEq/day over the final 3 days of the patient's life. Autopsy confirmed the findings at laparotomy, and disclosed multiple infarcts of the liver, especially the left lobe, and kidney, as well as occlusion of the inferior mesenteric artery at its origin.

9800 QUANTITATIVE DETERMINATION OF GASTRIC INTRINSIC FACTOR AFTER LARGE HISTAMINE DOSES IN HEALTHY PERSONS. (E.) Rødbro, P. (Bispebjerg Hosp., Copenhagen) and P. M. Christiansen. Scand. J. Clin. Lab. Invest. 19(2): 186-189, 1967.

Production of gastric intrinsic factor was determined in 30 healthy volunteers (20 men, 10 women; av. age 44 yr.) without previous dyspepsia after large doses of histamine. Gastric juice in 1 basal hr. and in four 15-min. periods after stimulation with 0.04 mg histamine diphosphate/kg was collected; 30 min. before the s.c. inj. of histamine, 100 mg mepyramine maleate was admin. i.m. Intrinsic factor was determined radioimmunologically as the difference between total-vitamin B_{12}-binding capacity in gastric juice and the vitamin-B_{12}-binding capacity after complete blockage of the intrinsic-factor-vitamin-B_{12} binding capacity with intrinsic-factor antiserum. The av. secretion of gastric intrinsic factor after augmented histamine stimulation was 15,400±6,650 ng vitamin B_{12} U/hr. A modification of the protein-coated charcoal assay for intrinsic factor, using a variable between amounts of gastric juice and vitamin B_{12}, is described in detail. In this method, a fixed amount of vitamin B_{12} (10 ng) is used, and the vitamin B_{12}/gastric juice ratio usually varies from 50-500 ng vitamin B_{12}/ml gastric juice (using 20-200 μliters gastric juice in the single test). With this adaptation of the amount of gastric juice according to vitamin B_{12} binding capacity present, the highest radioactivity is in most tests found in the charcoal sediment (= free vitamin B_{12}); therefore, the vitamin B_{12} content in the supernatant (= vitamin B_{12} bound to gastric juice) is calculated from the radioactivity of the charcoal and the radioactive standard (= 10 ng vitamin B_{12}). Sufficiently high counts per min. are thus obtained with minute amounts of radioactive material in each test.

9801 EFFECT OF L-HYOSCYAMINE ON GASTRIC SECRETION OF ACID AND INTRINSIC FACTOR IN MAN. (E.) Dotevall, G. (U. Goteborg, Sweden), A. Walan and A. We nfeld. Gut 8(3):276-280, 1967.

Vol., HCl production and intrinsic factor output were studied in human gastric juice (from 7 male patients with chronic duodenal ulcer without hematological abnormalities) basally and after infusion with increasing doses of histamine before and during treatment with L-hyoscyamine;
the latter is the most active component of
atropine. The vol. of gastric juice increased
successively in the first 4 periods of histamin
stimulation. In spite of a 3-fold increase in
histamine dose from the fourth to the sixth
period, no further increase of vol. occurred.
Output of HCl increased successively in the
first 5 periods of histamine stimulation. During treatment with optimal effective doses of
L-hyoscyamine (which varied between 0.2-1.0 mg,
with a mean of 0.57 mg), the vol. and output of
HCl were lower basally and during stimulation
with low doses of histamine. In the last peric
when the largest doses of histamine were given,
there was no change in output when compared to
the pretreatment values. Output of intrinsic
factor increased notably during histamine
infusion; the output was largest during the
first 45 min. of stimulation after which a sli
decrease occurred; output of intrinsic factor
75-90 min. after beginning of histamine infusi
was still higher than during basal conditions.
Treatment with optimal doses of L-hyoscyamine
resulted in a higher output of intrinsic facto
during the basal period but the increase durin
stimulation with low doses of histamine, which
was very marked before treatment, was less pronounced during treatment. Total output of
intrinsic factor was not changed during treatment with L-hyoscyamine for 3 wk. These resul
agree with the suggestions of a "wash-out"
phenomenon for intrinsic factor secretion afte
stimulation with histamine. The continued hig
output of intrinsic factor 75-90 min. after th
start of a histamine infusion could be the
result of a late "wash-out" response or a dire
stimulatory effect by histamine on intrinsic
factor production.

9802 PANCREATIC METABOLISM OF Se^{75} SELENOMETHIONINE IN DOGS. (E.)
Van Goidsenhoven, G. E. (St. Louis U. Sch. Med
Mo.), A. F. Denk, B. A. Pfleger and W. A. Knig
Jr. Gastroenterology 53(3):403-411, 1967.

Acute and chronic experiments were conducted i
25 mongrel dogs to study the fate of i.v. inj.
^{75}Se selenomethionine, with special reference
its pancreatic metabolism after stimulation wi
pancreozymin and secretin. Radioactivity befo
and after protein precipitation with trichloro
acid was measured in urine, plasma, bile and p
creatic juice; radioactivity was also determin
blood and stools. Hepatic and pancreatic upta
were estimated from tissue homogenates. Bioch
determinations were performed to allow correla
with observed changes in radioactivity. After
i.v. inj., most of the label rapidly disappeai
from the plasma with a low point at 30 min., a
secondary peak at 24 hr., and then a slow decl
over a period of wk. Initially the radioactiv
was found in the trichloroacetic-acid-soluble
tion, but after the fourth hr. it was recovere
almost exclusively from the trichloroacetic-ac
precipitate and could be demonstrated in every
protein electrophoretic fraction. The label

o appeared in the circulating RBC. Some of
s activity could be traced very early after
. In spite of a higher conc. of ^{75}Se
enomethionine in the pancreas, the total
atic uptake exceeded the total pancreatic
ake. Excretion of radioactivity in pancreatic
ce became appreciable 1 hr. after inj. and
found almost exclusively in the trichloro-
tic-acid precipitate. The label appeared in
e and the excretion was relatively constant
ng the first 4 hr.; initially most of the
vity was found in the trichloroacetic-acid-
ble fraction, but with time a greater propor-
appeared in the precipitate. Approx. 80%
he label was excreted in the urine and feces
he end of 12 wk. Analysis of these results
a review of the literature indicate that
-selenomethionine is widely utilized in the
for the formation of a variety of proteins;
tissues show preferential uptake of this
l, but organ specificity is lacking.

THE INTERACTION OF SECRETIN AND PANCREO-
ZYMIN ON THE EXTERNAL PANCREATIC
ETION IN DOGS. (E.) Henriksen, F. W. (U.
nhagen) and H. Worning. Acta Physiol. Scand.
):241-249, 1967.

reatic secretion of fluid, protein and
rbonate in 4 mongrel dogs with chronic Thomas-
fistulae was studied in response to secretin
/kg), pancreozymin (1 U/kg) and combined
etin-pancreozymin (1 U/kg of each agent).
rates of secretion of fluid, bicarbonate and
ein after combined, submax. stimulation were
ly reproducible, as indicated by the
ficients of variation of 1.7% (fluid), 3.9%
arbonate) and 5.1% (protein). Secretion
s of fluid and bicarbonate obtained after the
ined stimulation with secretin-pancreozymin
close to those obtained after isolated
ulation with max. doses of secretin. Secretin
pancreozymin were shown to have a potentiat-
effect on the pancreatic secretion of
rbonate, but only an additive effect on pro-
secretion.

INTRADUODENAL GLUCOSE INFUSION AND
PANCREATIC SECRETION IN MAN. (E.)
P. T. (McGill U., Montreal, Canada) and
. Preshaw. Lancet 2(7511):340-341, 1967.

dio-opaque double-lumen duodenal drainage
was inserted into the duodenum of each of
bjects, 1 of whom had a duodenal ulcer, and
her of whom had abnormal glucose tolerance.
r infusion of 0.15 M NaCl soln. for a con-
period of at least 1 hr., glucose soln.
ing from 2.5-20.0% were infused for consecu-
30-min. periods. Finally, 0.05 M citric
was infused for 30 min. Duodenal collec-
s were analyzed for bicarbonate and protein.
sion of glucose had no effect on the recovery
luid, bicarbonate or protein from the
enum, but in each case an infusion of citric
acid caused an increase in the recovery of fluid and bicarbonate. Gastric secretion was not stimulated by any test soln. It is concluded that intraduodenal infusion of glucose in man has no effect on external pancreatic secretion.

9805 POTENTIATION OF SECRETIN STIMULATION OF THE PANCREAS. (E.) Brown, J. C. (U. Newcastle upon Tyne Med. Sch., England), A. A. Harper and T. Scratcherd. J. Physiol. (London) 190(3):519-530, 1967.

Stimulation of the dorsal vagus trunk in fasted anesthetized cats (which were secreting pancreatic juice at a steady slow rate in response to continuous i.v. infusion of secretin) produced an increase in the rate of secretion, the rate of output of amylase and in the conc. of bicarbonate in the juice. Atropine reduced, but did not abolish, the increase in rate of secretion and in conc. of bicarbonate; it was unaffected by adrenergic blocking agents, but abolished by hexamethionium. No increase in rate of secretion of secretin-stimulated juice was noted on cervical stimulation of vagus nerves in which the efferent fibers had degenerated after supra-nodose section of the nerves. It is suggested that the increase in secretion rate is mediated by atropine-resistant efferent vagal fibers. The rate of secretion of secretin-stimulated juice was increased by histamine, antral extracts and pancreozymin. The latter two also increased the rate of amylase output. Atropine or hexamethonium did not abolish these effect of pancreozymin and antral extracts. Since vagal stimulation, histamine, antral extracts and pancreozymin have little or no effect on the resting pancreas of the anesthetized cat, it is concluded that they exert a potentiating effect on secretin; it is suggested that the mechanism of this potentiation is an increase in pancreatic blood flow, which facilitates the supply of secretin to the gland.

9806 STUDY OF PANCREATIC EXOCRINE SECRETION IN HUMANS AFTER TEST MEAL FEEDING. (It.) Dal Monte, P. R. (U. Bologna, Italy), E. Fiore, L. Lodi and R. Cremonini. Boll. Soc. Ital. Biol. Sper. 43(4):161-165, 1967.

The effects of p.o. feeding of a test meal (45 g skimmed milk; 45 g corn oil; 25 g glucose; brought to 300 ml by adding water) on pancreatic exocrine secretion were studied in 28 subjects of both sexes (age 23-57 yr.) with no evidence of gastrointestinal pathology. Subjects were fasted for 12 hr. before feeding; pancreatic juice samples were collected before feeding and after feeding (at 30-min. intervals for 2 hr.) by insertion of an Einhorn tube as far as the second portion of the duodenum and first portion of the jejunum. Trypsin determination was performed mainly by the Nagel spectrophotometric method; amylase determination by the Rice method. The av. vol. of pancreatic juice was 47 ml before feeding; after feeding, the av. vol. was

79 ml after 30 min., 101 ml after 60 min., 78 ml after 90 min., and 72 ml after 120 min., for a total av. secretion of 331 ml. Amylase levels (av.) were 19,900 mU before feeding, and 39,700 mU at 30 min., 42,600 mU at 60 min., 38,300 at 90 min., and 29,400 mU at 120 min. after feeding; total 150,000 mU. Trypsin levels (av.) were 1300 mU before feeding, and 2917 mU at 30 min., 3978 mU at 60 min., 2873 mU at 90 min., and 2861 mU at 120 min. after feeding; total 12,629 mU. Results indicate that the test meal admin. is a potent stimulus of pancreatic secretion and enzyme activity, with max. values of each observed 1 hr. after feeding. No washout of pancreatic enzyme activity was seen. The authors feel that the above method is a valid and sensitive way to study pancreatic exocrine secretion.

9807 THE EFFECT OF CRUDE SECRETIN IN MATURITY-ONSET DIABETES MELLITUS. (E.)

Persson, I. (Frederiksberg Hosp., Copenhagen), F. Juhl and D. Svendsen. Lancet 2(7513):445-446, 1967.

The effect of crude secretin (100 U) was studied in 5 groups of patients: 1) 27 with maturity-onset diabetes mellitus (46-83 yr. old; av. age 66 yr.; duration of diabetes ranged from 6 mo.-18 yr., av. 7 yr.; 8 patients were obese); 2) 5 with juvenile diabetes (av. age 30 yr., av. duration, 20 yr.; all were receiving insulin); 3) 13 patients who were obese and hypertensive, and thus predisposed to diabetes mellitus; 4) 9 with neurosis and arthritis, but no disposition to diabetes, and who served as controls; and 5) a control group of 6 patients with maturity-onset diabetes who received an i.v. inj. of insulin, 0.1 I.U., and glucagon, 400 ng (stabilized with albumin) in the same amounts as were present in the crude secretin. The results were analyzed by grouping the patients into 3 categories as follows: Group A, previously Groups 1 and 5; Group B, previously Group 2; and Group C, previously Groups 3 and 4. Group A showed a fall in the blood-sugar during the period of study, Group B had a rise, and Group C showed a 20-min. fall after which the blood-sugar reverted to the initial values. It is concluded that the fall in the blood-sugar level observed in maturity-onset diabetes, but not in the other groups, was due only to the secretin or to another substance in the duodenal extract; the control experiments showed that the effect was not due to insulin or glucagon.

9808 INTESTINAL HORMONES AND PLASMA INSULIN: AN INSULINOTROPIC ACTION OF SECRETIN.

(E.) Boyns, D. R. (Guy's Hosp., London), R. J. Jarrett and H. Keen. Brit. Med. J. 2(5553): 676-678, 1967.

The effect of endogenous secretion on the plasma immunoreactive response to i.v. glucose was studied in 5 healthy men, ranging in age from 25-40 yr. old. The effect of purified porcine secretin was compared with that of cholecystokinin/pancreozymin (1500 Ivy dog units/mg admin. as 50 μg/20 ml saline i.v. 1 ml/min.). I.v. admin. of purified secretion (20,000 clinical U/mg admin. as 6 μg/20 ml saline at 1 ml/min.) raised the level of fasting venous plasma immunoreactive insulin, and increased the immunoreactive insulin response to i.v. 5% glucose (20 g/hr.). By contrast, endogenous secretin (stimulated by intraduodenal infusion of 0.05 N citric acid instillation admin. 5 ml/min. for alternate min. for 20 min.) did not cause a rise Cholecystokinin/pancreozymin had no effect. Endogenous secretin did not augment the plasma immunoreactive insulin levels obtained during i.v. glucose infusion. It is believed that secretin is insulinotropic only in unphysiologic quantities.

9809 EFFECT OF TESTOSTERONE AND DUCT LIGATIO ON SUBMAXILLARY RENIN-LIKE PRINCIPLE.

(E.) Oliver, W. J. (CIBA, Ltd., Basel, Switzerland) and F. Gross. Amer. J. Physiol. 213(2): 341-346, 1967.

The renin-like principle of the submaxillary gland of the white mouse has greater activity in males than in females throughout the lifespan of 3-36 wk. Dependence of this difference on male sex hormone was demonstrated by 1) reduction in renin-like activity in males after castration; 2) restoration of activity in castrated males by therapy with testosterone; and 3) enhanced activity in females given testosterone treatment After ligation of the common submaxillary duct, renin-like activity decreased within 3 days; it was nearly undetectable after 7 days. These results suggest that the renin-like substance present in the mouse submaxillary gland is one of the androgen-dependent proteolytic enzymes of the excretory ducts and is associated with exocrine function of the gland. Its specific function is unknown.

9810 EXCRETION OF SODIUM AND POTASSIUM IN CAT SUBMANDIBULAR SALIVA. (E.)

Petersen, O. H. (U. Copenhagen) and J. H. Poulse Acta Physiol. Scand. 70(2):158-167, 1967.

Cat submandibular gland secretion was elicited by chorda stimulation, and the conc. of Na and K in the saliva were determined by flame photometr Na conc. in the initial samples of cat submandibular saliva taken from a previously resting gland were higher than the Na conc. in samples taken later at an identical secretory rate. The max. difference in conc. between transient and steady-state sample was approx. 50 mEq/liter. Steady state conc. of Na increase proportionally to the flow rate, except at low flow rates where Na conc. were greater than expected on the basis of this relation. Steady state conc. of K were independent of the secretory rate when this was higher than 100 μliters/min./g of gland, with a value of approx.

mEq/liter. Below this flow rate, the K conc.
se, first slightly and then steeply, when flow
te decreased, and reached values of more than
0 mEq/liter at secretory rates of approx.
μliters/min./g of gland.

11 IMPULSE FREQUENCY IN SECRETORY NERVES OF SALIVARY GLANDS. (E.)

Emmelin, N.
. Lund, Sweden) and J. Holmberg. J. Physiol.
ondon) 191(1):205-214, 1967.

dogs under pentothal anesthesia the sub-
xillary duct was exposed in the neck and a
lythene tube inserted into it; during the
llowing days, the animals were examined re-
atedly, standing in a frame. The highest rates
submaxillary secretion evoked by introducing
rious foodstuffs or rejectable substances into
e mouth were estimated. Finally, the dogs were
esthetized and the rates of salivary flow were
ecorded during electrical stimulation of the
ordalingual nerve at different frequencies.
e frequency-response curve for electrical
imulation had a steep slope up to a frequency
10/sec., where a salivary flow at a rate of
oprox. 90% of the max. was evoked. The fastest
ecretion that was obtained reflexly on feeding
orresponded to a flow which in different experi-
ents varied between 4 and 8 shocks/sec. The
apid secretion caused by rejectable substances
ould be reproduced by stimulating at 10-30/sec.
similar experiments on the parotid gland
oodstuffs were often, and rejectable substances
lways, found to cause a salivary flow at a rate
at exceeded that obtained on max. stimulation
f the auriculotemporal nerve; the finding
upports the view expressed by previous investi-
ators that additional secretory fibers reach
he parotid gland of the dog by anatomically
nknown routes.

812 PATTERN OF SECRETION OF PANETH CELLS OF THE SMALL INTESTINE OF MICE. (E.)

rier, J. S. (U. Wisconsin, Madison), V. Lorenzsonn
nd K. Groehler. Gastroenterology 53(2):240-249,
967.

he pattern and rate of secretory granule synthesis
nd secretion was studied in adult male white
ice after fasting, feeding and pharmacological
oses of atropine (4 mg dissolved in 0.4 ml of
.9% NaCl, admin. i.p.) and pilocarpine (0.5 mg
issolved in 0.5 ml of 0.9% NaCl, admin. i.p.).
ice were sacrificed 15 min.-24 hr. after receiv-
ng L-leucine-3H i.p. to pulse label newly
synthesized protein. Microautoradiographs of
smium-fixed, epoxy-resin embedded jejunum were
repared to follow the intracytoplasmic location
of label. Distribution of radioactivity within
Paneth cells was determined quantitatively using
coded, randomized slides without foreknowledge
regarding the source of tissue specimens. After
leucine-3H admin. to fasted mice, label was most
abundant in the basally located endoplasmic
reticulum after 15-30 min., in the Golgi region after 1 hr., and in the apical cytoplasm of Paneth cells after 5-6 hr. By 12 hr., over 90% of Paneth cells no longer had significant labeling. Feeding of a diet containing fat, protein and carbohydrate did not stimulate granule synthesis or secretion. Pharmacological doses of pilocarpine enhanced both synthesis and secretion. Atropine inhibited secretion, but did not appear to interfere with normal granule synthesis. These observations provide firm evidence that Paneth cells not only have great secretory potential, but are characterized by continuous synthetic and secretory activity, even in fasted mice. This active basal secretion was not enhanced by feeding under the present experimental conditions, but was stimulated by pilocarpine and inhibited by atropine.

9813 PERIODIC SECRETION OF INTESTINAL GLANDS IN DOGS UNDER EMOTIONAL STRESS. (Rus.)

Maevskaia, N. V. (Donets Med. Inst., USSR) and Y. V. Linevskii. Biull. Eksp. Biol. Med. 63(5): 15-17, 1967.

Emotional stimulation lasting 60 min. in 2 dogs and 4 hr. in 1 dog was induced by showing the dogs a cut during the second hr. or throughout the experiment. Thiry or Thiry-Vella isolated fistulas were made in the initial part of the jejunum. During normal conditions enterokinase activity varied between 20-506 U/g homogenate, phosphatase content fluctuated between 900-25000 U and the enzyme excretion/1 hr. was more stable. After 60 min. or 4 hr. of aggressive reaction periodical secretion from the intestinal glands was significantly increased; in dogs with a longer aggressive reaction the secretion increased and was especially marked 2 days after emotional stimulation. In the dog with shorter aggressive reaction enzyme secretion increased due to marked increased conc. in juice. Total amount of secretion was in the region of control values, however, secretion of the solid part of the juice was 0.93 g/4 hr. as compared to 0.08-0.47 g in controls; enzyme content/g of the solid part of the juice increased approx. 2-fold. In the dog with longer aggressive reaction, enzyme excretion after emotional stimulation was not accompanied by conc. changes in the juice since there was a marked increase of separation of the fluid part of intestinal juice at that time. Enterokinase and phosphatase secretion usually changed in parallel to each other.

9814 THE INFLUENCE OF GASTRIN ANALOGUES AND 2-DEOXY-D-GLUCOSE ON BILE SECRETION. (E.)

Konturek, S. J. (Med. Sch., Cracow, Poland), A. Kieta-Fyda and K. Moczurad. Amer. J. Dig. Dis. 12(9):955-961, 1967.

Adult cats were prepared with gastric and biliary fistulas, and the influence of the following stimulants upon bile secretion was assessed: 2 gastrin analogs (a pentapeptide and a tetrapeptide), histamine, 2-deoxy-D-glucose, and saline. Both gastrin analogs and histamine effectively stimulated hepatic bile flow, the peak response being reached in the second or third 30-min. period. There was no difference between the responses to pentapeptide in doses ranging from 20-80 μg/kg; this was also true when either half or twice the dose of tetrapeptide was used. Admin. of 2-deoxy-D-glucose or saline alone did not result in any change in hepatic bile flow. A significant increase of bicarbonate output was found only after tetra- or pentapeptide inj. Histamine and 2-deoxy-D-glucose were ineffective in bicarbonate stimulation. Usually a slight increase of bicarbonate conc. occurred after application of the gastrin-related peptides, whereas no change or decrease was observed after histamine or 2-deoxy-D-glucose admin. No significant change in Cl output or conc. occurred after inj. of any stimulant; bile salt outputs were also not significantly influenced by the stimulants admin. They showed a progressive decline caused by bile drainage to the outside and the resulting interruption of their enterohepatic circulation. The pH level of the duodenal contents was 7.62 ± 0.15.

31 STUDIES ON INTESTINAL DIGESTION OF
STARCH IN MAN. II. INTESTINAL
DROLYSIS OF AMYLOPECTIN IN INFANTS AND CHILDREN.
) Auricchio, S. (U. Naples, Italy), D. Della
etra and A. Vegnente. Pediatrics 39(6):853-862,
57.

ne normal infants and 4 children between the
es of 2.5 and 28 mo. were fed powdered milk to
ich dextro-maltose and (from the beginning of
e 4th mo.) 4 g of flour/kg of body wt. had been
ded. Starchy foods were given from the end of
e fourth mo. Also examined was a 26-mo.-old
ild with exudative enteropathy of unknown etiol-
/ who had been treated successfully for the
st 3 mo. with prednisolone. The test meal con-
ined amylopectin (about 9 g/100 ml), casein
g/100 ml) and vegetable oil (4 g/100 ml) and
epared by dissolving, without heat, 50 g of
ylopectin in 500 ml H_2O by shaking for 60 min.
infants at the end of the first yr. of life
d in small children the amylopectin is very
pidly hydrolyzed into glucose, maltose, malto-
iose, and branched dextrins; these compounds are
kely hydrolyzed into glucose by the action of
cosal glucosidases. Infants up to 6 mo. of
e showed incomplete intestinal hydrolysis of
ylopectin with an accumulation of considerable
ounts of dextrins in excess of 30 glucose U.
ong the small oligosaccharides, a decrease in
e glucose and maltose content as well as an
crease in the maltotetraose content was noted.
e incomplete digestion of amylopectin is a con-
quence of the low levels of α-amylase activity
duodenal juice after the meal. In contrast,
e mucosal α-disaccharidases, with the single
ception of maltase I, are already present at
ult levels in the newborn. The incomplete
amylolysis of starch in the duodenum would be
pected to give a relatively high frequency of
arch malabsorption in the first yr. of life
cause in such young children the intestine
obably has little reserve capacity for the
gestion of starch.

32 LACK OF PROTEOLYTIC DIGESTION IN THE CAUSATION OF PERNICIOUS ANAEMIA. (E.) Mooney, F. S. (St. Helen's Hosp., Lancashire, England) and J. G. Heathcote. Lancet 2(7512): 397-399, 1967.

Experimental evidence is presented that, in casein, vitamin B_{12} is almost entirely bound to the protein in a non-dialyzable form, and that progressive release of the bound vitamin occurs simultaneously with the release of α-amino N under the influence of alimentary proteases. This in vitro evidence suggests that the release of vitamin B_{12} from bound protein and digestion of the protein itself to smaller components occur simultaneously and progressively in a logical manner. These findings do not support the view that the vitamin binds itself to any large molecule during the normal stages of digestion, but rather they support a previously expressed concept that the primary cause of pernicious anemia is merely a lack of proteolytic digestion.

9838 NERVOUS FACTORS INFLUENCING THE MEMBRANE ACTIVITY OF INTESTINAL SMOOTH MUSCLE.

(E.) Kuriyama, H. (Kyushu U., Japan), T. Osa and N. Toida. J. Physiol. (London) 191(2):257-270, 1967.

The effects of various chemical agents on the spontaneous membrane activities and those elicited electrically in the smooth muscles of the small intestine (chiefly, longitudinal muscle of the jejunum of the guinea pig) were studied. With regard to the effects of various chemicals on the spontaneously active membrane, atropine slightly hyperpolarized the membrane and reduced the amplitude of slow potential changes, even in aged preparations. Prostigmine depolarized the membrane, and enhanced the amplitude and prolonged the duration of the slow potential changes. Atropine prevented the actions of prostigmine on the membrane. Ba ion depolarized the membrane, and enhanced the amplitude and prolonged the duration of the slow potential changes; the spike frequency was initially increased, and then it was reduced. Atropine and tetrodotoxin partially prevented the action of Ba ion on the membrane activities. Effects of chemical agents on the membrane activity elicited by electrical stimulation showed that short pulse stimulation (0.5-1.0 msec.) generated the spike as a direct response of the muscle cell membrane, then it was followed by slow depolarization, delayed hyperpolarization (i.e., the inhibitory potential) and post-inhibitory rebound, successively. The slow depolarization and the post-inhibitory rebound were reduced in amplitude by treatment with atropine, and enhanced by treatments with prostigmine and Ba ion. Tetrodotoxin blocked all activities, except the spike. When repetitive stimulation (20 cycles/sec.) was applied to the membrane, the membrane hyperpolarized; then, after 3-5 sec., it gradually depolarized (even if the stimulation was continued) and triggered spikes. Hyperpolarization always preceded depolarization. The duration and the amplitude of the delayed depolarization was proportionally increased by the increased intensity and duration of stimulation. Tetrodotoxin and atropine blocked the generation of the post-inhibitory rebound. The effects of repetitive stimulation on the stored tissues were noted; the responses to repetitive stimulation of the membrane of muscles which had been stored 50 hr. at 4°C were the same as those observed in the fresh tissue. Response of tissue which had been stored 100 hr. was the same as that observed in the fresh tissue treated with tetrodotoxin, i.e., all activities, except the spikes, were blocked.

9839 ELECTROPHYSIOLOGICAL STUDY OF THE INTESTINAL SMOOTH MUSCLE OF THE GUINEA-PIG.

(E.) Kuriyama, H. (Kyushu U., Japan), T. Osa and N. Toida. J. Physiol. (London) 191(2): 239-255, 1967.

The membrane properties of single cells of intestinal smooth muscle of duodenum, jejunum, ileum, cecum and rectum of the guinea-pig were investigated. The membrane potentials of longitudinal muscles of these 5 regions varied from 54-56 millivolts, and those of circular muscles of jejunum, ileum, cecum and rectum varied from 57-60 millivolts. The ablated longitudinal musc had a slightly lower value (50 millivolts) than the intact one. Longitudinal muscle generated spontaneous discharges but these were rare in th circular muscles of the intestine, except for the cecum. Overshoot potentials could be observ in all regions of the intestine. The max. rate of rise of spontaneously discharging longitudina muscles varied from 11-18 volts/sec. Not all of the slow potential changes were generated by the nervous elements distributed between the muscle layers and in them. Conduction velocities measu from the longitudinal muscles of jejunum and rec in the presence of tetrodotoxin were 2.1 cm/sec. and 4.0 cm/sec., resp. Chronaxies of the longitudinal muscles of jejunum and rectum were 2-5 msec. and 5-18 msec., resp. Intracellular stimulation of the single cells of the duodenum and cecum could trigger a spike, similar to that observed in the taenia coli. Most of the spikes were graded; a spike of full size was rarely elicited. When spikes were triggered, the after-hyperpolarization appeared consistently, presumably caused by the increased K conductance. The effective membrane resistance and the time constant were measured for the longitudinal muscles of the rectum and jejunum; when spikes were generated by intracellular stimulation, the observed values were 40-50 megohms, and 3-5 msec. in both tissues; these values were the same as those seen in the taenia coli. When the time constant of the membrane was measured by the extracellular polarizing method, the longitudina muscles of the jejunum (especially) and the rect had smaller time constants than the taenia coli. The differences of conduction velocity and chronaxie of the different regions of the intestine are discussed in relation to the cable propertie of the tissues which are directly influenced by the morphological arrangements of the tissues.

9840 EFFECT OF CHOLECYSTOKININ ON SMALL INTESTINE.

(E.) Hedner, P. (U. Hosp., Lund, Sweden), H. Persson and G. Rorsman. Acta Physiol. Scand. 70(2):250-254, 1967.

The effect of highly purified cholecystokinin on gallbladder and intestine (ileum) was studied *in vivo* (on 10 cats of either sex) and *in vitro* (on 65 guinea pigs of either sex). The purified cholecystokinin preparation contained 4000 Ivy dog U/mg; and a crude preparation contained 200 U/mg. The purified preparation caused a contraction of the guinea pig ileum which was proportio to the dose admin.; activity of the purified preparation was 21.8 times greater/mg than that of the crude preparation. Atropine in doses of approx. 0.1 µg completely inhibited responses of

 acetylcholine and of 4 U of cholecystokinin.
honium in doses up to 100 μg did not affect
ponse to cholecystokinin. Guinea pig gall-
 responded to cholecystokinin in lower doses
ose required to obtain a contraction of the
 the lowest effective dose was 0.3 Ivy dog
lay of the response was seen, and with in-
g doses the lag period decreased. Atropine
se of 0.2 μg, which inhibited the response
 acetylcholine, left the response to 0.6 U
ecystokinin unaffected; no reduction of the
e to cholecystokinin could be observed,
ter an increase of the atropine dose to
 In vivo experiments showed that after
 of cholecystokinin admin. i.v. (4000 Ivy
g), the gallbladder pressure increased from
 2 mm Hg to approx. 10 mm Hg. Pressure in
junum usually did not exceed 15 mm Hg in
trol period; after cholecystokinin the basic
as elevated approx. 10 mm Hg above the con-
vel, and there were frequent pressure peaks
t duration up to 55 mm Hg. After treatment
ropine (2 mg/kg) the intestinal response to
stokinin was inhibited but the response of
lbladder remained completely unaffected.
oncluded that the contraction of the small
ine elicited by cholecystokinin preparations
 to the hormone itself and not to impurities
 preparations; this intestinal effect is
ed by another mechanism of action than the
 of the hormone on the gallbladder; chole-
inin in low conc. appears to have a specific
 on the proximal part of the intestine. It
sible that the hormone may play a role in
gulation of intestinal motility.

MECHANICAL RESPONSES OF INTESTINAL SMOOTH
MUSCLE IN A CALCIUM-FREE MEDIUM. (E.)
z, L. (Vanderbilt U. Sch. Med., Nashville,
, P. D. Joiner and S. Von Hagen. Proc.
xp. Biol. Med. 125(2):518-522, 1967.

udinal fibers from guinea-pig ileum under-
 transient increase in muscle tone when they
ransferred from a physiological salt soln.
a-free soln.; composition of the physiological
oln. was as follows: NaCl, 125 mM; KCl,
; $CaCl_2$, 1.8 mM; glucose, 11 mM; and tris
hydroxymethyl)aminomethane, Sigma-trizma
 buffer, 23.8 mM. The magnitude and duration
 contractile response was enhanced if the
 was preincubated in a high Ca medium
). The length of time that the muscle was
ubated in the high Ca medium influenced the
ude of the response, as well as the amount
racellular Ca accumulated by the fibers.
chanical changes initiated by removing ex-
lular Ca ions were accompanied by a pronoun
d increase in the unidirectional efflux of
s. The addition of acetylcholine or a high
um (identical in composition to the physio-
l salt soln., except that all the NaCl was
ed by an equimolar quantity of KCl) enhanced
ne of a muscle that was partially contracted
a-free medium. The addition of 1.8 mM
 depressed it. However, when the same conc.
of $CaCl_2$ was added in the presence of acetylcholine or a high K medium, it enhanced muscle tone even more. It is suggested that acetylcholine, a high K medium and a Ca-free medium, by increasing membrane permeability, accelerated the migration of Ca ions from an intracellular locus to the cytoplasm; these findings also suggest that they accelerate the movement of Ca ions between the external soln. and the cytoplasm of the muscle fiber.

9842 ELECTRICAL PROPERTIES OF INTESTINAL MUSCLE AS MEASURED INTRACELLULARLY AND EXTRACELLULARLY. (E.) Kobayashi, M. (U. Illinois, Urbana), C. L. Prosser and T. Nagai. Amer. J. Physiol. 213(1):275-286, 1967.

In vitro measurements of electrical properties were made on muscle of duodenum or jejunum from cats, and in vivo measurements were made on intestines of dogs. Slow waves recorded extracellularly by wicks in air or by implanted wires in vivo were positive, just as those recorded intracellularly by pressure or microelectrodes; wicks recorded negative slow waves in vol. conditions. Unlike slow waves, spikes reversed polarity between inside and outside in air or implantation. Slow-wave amplitude was max. in the middle of the muscularis. Failure of polarity reversal may have been due to pressure effects of wick or implanted wire, and also to source-sink relations within fields of synchronous activity. Resistance of longitudinal muscle fibers was 52 megohms, that of quiescent circular fibers was 68 megohms, and that of circular fibers showing induced slow waves was 58 megohms. Resistance between adjacent longitudinal fibers was 16 megohms, specific protoplasmic resistance was 222 ohms cm. The time constant with intracellular electrodes in a bridge circuit was 10 msec. for longitudinal fibers, 21 msec. for circular fibers. With extracellular or pressure electrode stimulation, time constants were 52-105 msec. for longitudinal fibers. Space constants measured with extracellular stimulation were 1-1.5 mm, whereas those calculated for intracellular stimulation were 118 μ. With paired intracellular electrodes of 7-70 μ, separation electrotonic coupling was 70-80%, at wider separations it approached 0. It is concluded that the effective conducting unit appears to be a bundle rather than a chain of single cells.

9843 CONFIGURATION OF INTESTINAL SLOW WAVES OBTAINED BY MONOPOLAR RECORDING TECHNIQUES. (E.) Bortoff, A. (State U. New York Upstate Med. Ctr., Syracuse). Amer. J. Physiol. 213(1):157-162, 1967.

In vitro and in vivo recordings of intestinal slow waves in cat jejunum, made with extracellular, monopolar electrodes, showed that the so-called intermediate form of the wave consisted of an abrupt positive deflection followed by a negative notch and then by a somewhat more positive plateau that gradually subsided to the original potential level. The phenomenon resulted from a combination or superposition of the propagated monophasic slow wave and its associated field potential. Which form predominated depended on the relative magnitude of the shunting resistance around the tip of the recording electrode. When the shunting resistance was high, the monophasic form, representing the temporal course of membrane potential, predominated; as shunting resistance decreased, the field potential, representing the temporal course of membrane current, became predominant. It is concluded that the intermediate form of the wave can not be interpreted in terms of electrical changes at the membrane level unless the time courses, polarities and magnitudes of each of these components are known.

9844 CHARACTER OF CONTRACTIONS AND RATE OF TRANSIT OF CHYME IN THE SMALL INTESTINE DURING THE USE OF DIFFERENT TYPES OF FOOD IN THE NORMAL AND IN SOME PATHOLOGICAL CONDITIONS OF THE CECUM AND RECTUM.

(Uk.) Gubkin, V. A. (Shevchenko U., Kiev, USSR). *Fiziol. Zh. (Kiev)* 13(3):338-343, 1967.

Study was on 2 dogs (10-11 kg wt.) with fistulas in the upper part of the jejunum and ileum and with small parts of these segments covered from the side of tunica serosa with fine lead shot, which was covered by a layer of Plexiglass. Study of the character of contractions and velocity of progress of the chyme in the jejunum and ileum during feeding (food of different consistency containing proteins, or carbohydrates, or fats) in normal dogs or those with proctitis (provoked by repeated admin. of 20-30 ml of 10% soln. $AgNO_3$ into rectum) and appendicitis (provoked by repeated admin. of 3-5 ml of 10% $AgNO_3$ soln. into cecum) showed that motility of the jejunum and, to some degree the ileum, depends basically on the physical, and to a significantly lower degree on the chemical characteristics of the food. Fats markedly changed the motility of the small intestine. The contraction amplitude of the small intestine was greater after food consumption in lumps and lower after feeding with ground or liquid food. After feeding with protein and carbohydrate food a biphasic character of nutritional motility was evident in the jejunum, while in the ileum the phases were poorly expressed. The first phase (starting immediately after feeding) is characterized by a greater motility in the jejunum than the second phase. The transit speed of chyme in small parts of the jejunum and ileum depended little on the type of food, but the total time of the progress of the content from the duodenum to ileum with various types of food is different. In the case of proctitis and appendicitis the dynamics and character of contraction were disturbed as well as the velocity and dynamics of chyme transit in the small intestine.

9845 RELEASE OF A BRADYKININ-LIKE SUBSTANCE ON NERVOUS STIMULATION OF A FROG STOMACH MUSCLE PREPARATION.

(E.) Singh, I. (Med. Coll., Agra, India). *Arch. Int. Physiol* 75(2):211-217, 1967.

The isolated and perfused stomach (with attach vagus nerve) of *Rana tigrana* was allowed to release polypeptides spontaneously into Tyrode a DeJalon soln., then the vagus was stimulated w rectangular pulses of 0.5 msec. at 10 volts at shocks/sec. for 1 hr. in order to study polypeptides released by the nerve. The soln. wer tested for polypeptides on guinea pig ileum, r bit small intestine, and rat duodenum. Stomac contraction was also studied by stimulating th vagus for 30 sec. with rectangular pulses of 0 msec. duration at 10 volts and 12 shocks/sec. Vagal stimulation released neurokinin (substan P) and a bradykinin-like substance, and produc 2 types of contraction, one of which could be abolished with acetylsalicylic acid. This suggested the polypeptide's role as transmitter. nature of the other type of contraction was unknown.

9846 PRESENCE AND RELEASE OF PROSTAGLANDI IN THE RAT STOMACH.

(It.) Coceani, (U. Bologna, Italy), C. Pace, F. Volta and L. Wolfe. *Boll. Soc. Ital. Biol. Sper.* 43(2):76- 1967.

Various experiments were performed to determin the presence and mode of release of prostaglan in the rat stomach. A substance with properti similar to those of the prostaglandins was isol from rat stomach perfusates obtained according to the Paton-Vane method and differed from othe biologically active substances in the followin acts on stomach preparations pretreated with atropine and methysergide (1×10^{-7} g/ml); is r destroyed by incubation with chymotrypsin (100 µg/ml) for 30 min. at pH of 8.5 and 37.5°C; is separated at pH of 2 in ethyl ether but not in petroleum ether boiling interval 30-60°C). Chromatography (Green-Samuelsson method) reveal that the prostaglandins present in the perfusat were mostly of the E type (especially E_2) with very small amounts of the F type ($F_{1\alpha}$ and $F_{2\alpha}$). Prostaglandins of identical chemical structure were also present in stomachs entirely removed. The amount of prostaglandins released *in vitro* amounted to 0.3 ng/min. (activity expressed in equivalents of prostaglandin E_1) and increased to 0.7 and 1.1 ng/min. after 5 counts/sec. and 10 counts/sec., resp., of vagus stimulation. T amount of prostaglandins liberated did not chan following stimulation of postganglionic sympath fibers. Experiments conducted on stomach prepa tions preserved in Tyrode's soln. for 3 days at 2-3°C, and consequently without nerve endings, revealed that prostaglandins were released at the level of the muscular layer and in the same amounts as in fresh stomach preparations at res Results indicate that prostaglandins as such or in the form of precursors or metabolites play a role in the regulation of gastric motility. Results also seem to indicate that the shifting o ons in the muscular layer is one of the major, ot the major, mechanism explaining the spasmo- : effect of the prostaglandins.

MECHANISM OF ACTION OF PENTAZOCINE ON GASTROINTESTINAL MOTOR FUNCTION. (E.)
of, I. E. (U. Texas Southwestern Med. Sch., as) and W. P. Blackmore. Toxic. Appl. nacol. 10(2):223-232, 1967.

izocine was admin. in doses of 0.5-3.0 mg/kg nesthetized and unanesthetized dogs, and was sociated with a change in the rate of slow- potentials in the pyloric antrum from the il 4-5 waves/min. A decrease in slow-wave gation velocity in the proximal pyloric an- was observed after the drug, leaving un- ged the propagation velocity in the distal of pyloric antrum. The pyloric sphincter apparently unaffected by pentazocine in the s utilized in these studies. Additionally, izocine was associated with a transient in- e in action potentials (spiking) and an in- e in amplitude of duodenal motility leaving fected the normal duodenal slow-wave rate of ox. 17-19/min. Immediately after this, spik- nd duodenal motility were abrogated and the enal tone was markedly diminished. Respiratory was diminished and the pattern showed ir- arities after pentazocine. It is suggested the interposition of a normal distal pyloric ent between the proximal pyloric antrum above the immobile and hypotonic duodenum below wed pressure gradients to develop which im- d the normal rate of gastric emptying.

COMPARISON OF THE EFFECTS OF A GASTRIN EXTRACT AND A SYNTHETIC PENTAPEPTIDE
ASTROINTESTINAL MOTILITY IN THE CAT. (E.)
/, J. (St. Bartholomew's Hosp., London).
3(3):242-248, 1967.

ne anesthetized cat whose anterior abdominal was replaced by a transparent window, the cts of gastrin and I.C.I. 50,123 [a synthetic apeptide] on the motility of the stomach, l intestine and colon were compared both be- and after sympathetic blockade and after renergic blockade, β-adrenergic blockade, and pine and mepyramine maleate admin. Gastro- stinal motility was evaluated both visually by means of a gastric balloon and fluid-filled s placed in the small intestine. Gastrin pro- d minimal motility in the stomach and motility onses of similar magnitude in the small in- ine and colon. The gastrin effect on the l intestine and colon was potentiated by α- β-adrenergic blockade, resp. Atropinization lted in no change in gastrin effect except r both α- and β-blockade. The motility ef- s of gastrin were unaffected by mepyramine n. I.C.I. 50,123 did not produce any effect otility in the small intestine. In the pinized cat, the motility effect of I.C.I. 23 on the colon was significantly reduced and negligible and no effect on stomach and small intestine motility was noted, resp. Motility effects of I.C.I. 50,123 on all areas were enhanced following admin. of atropine and following both α- and β-adrenergic blockade.

9849 GASTRIN AS AN INTESTINAL ACTIVATOR. (E.) Logan, C. J. H. (Queen's U., Belfast, N. Ireland). Brit. J. Surg. 54(4): 297-301, 1967.

In the described work, I.C.I. 50,123 (N-t-butyloxy-carbonyl-β-alanyl-l-tryptophyl-l-methionyl-l-aspartyl-l-phenylalanine amide, a pentapeptide with similar physiologic activity as gastrin) is used, employing pure gastrin to compare the effects of the 2 substances. The intraluminal pressure in the gut of mongrel dogs was measured by miniature balloons connected to a metal capsule optical manometer. Three balloons 5 cm apart were used in the colon while 1 was used in the Thiry fistula where the ileal motility was measured. A polythene cannula in a vein in the back leg of each dog was kept patent by an infusion of normal saline. During 3 min. i.v. inj. were given, and on 14 occasions a consant infusion of I.C.I. 50,123 was given, using an infusion pump. Six. inj. of Gastrin II were given to 3 dogs. With 0.25 μg/kg and 0.5 μg/kg there was increased activity in the colon and rectum of 1 dog whereas 0.5 μg/kg admin. twice to another dog had no effect. With 1.0 μg/kg given on 2 occasions there was increased activity in the rectum once and twice in the colon with 23 inj. of I.C.I. 50,123 given to 5 dogs, 1 of 4 inj. (0.125 μg/kg i.v.) increased colonic motility. Three of 4 inj. of 0.25 μg/kg increased motility in the colon and rectum. No obvious rise in activity was observed with increased dosage. Prolonged infusion of I.C.I. 50,123 (0.25 μg/kg.-2.0 μg/kg/min. given over 15-60 min.) caused increased motility in the colon and rectum, and slackening in intensity after 10 min. Dog meat (500 gm p.o.) showed a marked increase in colonic motility within 5 min. of food consumption. Five min. after i.v. inj. of pure gastrin (0.125-0.5 μg/kg) motility of ileal Thiry fistula was increased, decreasing in the second 5 min. after inj. of 0.25-0.5 μg/kg. I.C.I. 50,123 did not show an overall effect on the motility of ileal Thiry fistulae although prolonged infusion (0.5-1.5 μg/kg) caused increased motility.

9850 GASTROESOPHAGEAL SPHINCTERIC PRESSURES BEFORE AND AFTER ORAL ANTICHOLINERGIC DRUG AND PLACEBO ADMINISTRATION. (E.) Kelley, M. L., Jr. (U. Rochester Sch. Med., N. Y.) and H. L. Friedland. Amer. J. Dig. Dis. 12(8):823-833, 1967.

Resting pressures in each 0.5 cm segment of the gastroesophageal sphincter were measured in 24 presumably healthy persons (12 men, 12 women; 21-42 yr. old; mean age, 27.6 yr.) before and after 1 wk. p.o. admin. of valethamate bromide

(20 mg, 4 times a day), an anticholinergic with muscle-relaxing properties, or a placebo (which contained 80 mg of lactose) of identical appearance. The double-blind technic was used, with 12 subjects in each group. Pressures were detected by a 5- x 5-mm water-filled balloon and laterally notched, water-filled polyethylene tubes attached to extracorporeal transducers and measured at end inspiration and end expiration. No significant pressure alterations in either the open-tip or balloon tracings were recorded in subjects who ingested valethamate bromide. In those who received the placebo, a decrease in open-tip pressures was recorded in the infrahiatal segments, the change being most apparent at end inspiration. Pressures registered by the balloon in the placebo group were not similarly altered.

9851 REFLUX PANCREATOGRAPHY. AN EXPERIMENTAL STUDY IN MONKEYS. (E.) Doppman, J. (NIH, Bethesda, Md.) and R. H. Johnson. Invest. Radiol. 2(2):113-118, 1967.

Eleven of 13 Rhesus monkeys (Macaca mulatta) were subjected to the following surgical procedure: after a midline abdominal incision, umbilical tapes were placed about the duodenum at the pylorus and at the ligament of Treitz, isolating the ampulla of Vater within a closed duodenal loop; before ligation of the pyloric end, a urethral catheter was introduced through a gastrotomy incision and its tip positioned in the second duodenum; the abdomen was then closed and the urethral catheter brought out through the incision, allowing for inflation of the loop and monitoring of the intraduodenal pressure. The animals were then divided into 3 groups. In Group 1, the experimental group of 8 monkeys received secretin (20 clinical U) and cholecystokinin-pancreozymin (75 Ivy dog U of cholecystokinin and 300 Crick, Harper and Raper U of pancreozymin) intraduodenally over 2-3 min. The duodenal loop was inflated with Conray 60, and distention at 40 cm water was carefully maintained throughout the experiment. Reflux of contrast material into the pancreatic and biliary ducts occurred after secretin-cholecystokinin stimulation in 7 of 8 monkeys; reflux appeared at various times between 2 and 120 min. after duodenal distention; the pancreatic duct always filled first, and the process was a gradual retrograde opacification of the pancreatic duct over 1-2 min. All refluxing animals, except 1 (not evaluated) showed gross and microscopic evidence of pancreatitis; the most severe changes were found in animals with prolonged reflux and extensive alveolarization of the contrast material. Amylase levels postoperatively were elevated in all of the refluxing animals except 1. Group B consisted of 3 animals handled in an identical manner to th
of Group A, except that they did not receive secretin or cholecystokinin-pancreozymin; the duodenal segments of these animals were disten
arbitrarily for 3 hr. at 40 cm water. There wa
no reflux, the pancreas was normal and amylase levels at 1, 6 and 24 hr. postoperatively were also normal. Group C consisted of 2 animals w
were not operated upon, but who were given ide
tical doses of secretin and cholecystokinin-pa
creozymin; normal amylase levels were found in
these animals, and their pancreas was normal.
is concluded that reflux of duodenal contents
the pancreatic and biliary duct systems of mon
can be produced when intraduodenal pressure is
raised and the gastrointestinal hormones, secr
and cholecystokinin, are given. Whether reflu
is due to a direct relaxant action of cholecys
kinin upon the ductal sphincters or occurs dur
the periodic discharge of bile and pancreatic
secretion after hormonal stimulation is unknow

9852 THÈ ADRENOTROPIC RECEPTORS IN THE INTESTINE (ON THE MOTOR RESPONSE OF GUINEA PIG ILEUM). (E.) Ando, J. (Osaka Med. Coll., Japan) and K. Shiozu. Bull. Osaka Med. Sch. 13(1):1-3, 1967.

STRUCTURE OF REGENERATED LIVER FOLLOWING
RESECTION IN RATS OF DIFFERENT AGES.
Sidorova, B. F. (Inst. Exp. Biol., Acad.
i., Moscow). Biull. Eksp. Biol. Med. 63(1):
1967.

f rats (5-7/age group) after partial
tomy (66% of total organ wt. was removed)
age 7 and 14 days only slightly differed
at of intact rats (controls; 4-5/age group)
ifice 1.5 mo. after surgery. Most of the
lobes were the same size (e.g. Class 1 -
f 140-240 mm^2 surface; Class 2 - 260-360
ass 3 - 380-480 mm^2; Class 4 - 500-600 mm^2,
ers), e.g., Classes 1-4 predominated over
, as in controls Classes 1-3 predominated
ass 2. A greater number of Class 3 and 4
as compared to controls, showed that in
egeneration new hepatic lobes developed
y also became hypertrophic. In rats having
hepatectomy at the age 24-28 days and
ced 6 mo. later, the lobes were 2-3 times
than controls; they were mainly of Classes
compared to Classes 1-4 in controls. The
size of lobes in treated rats is conditioned
rgement in the process of liver growth.
her similar experiment (except both 10 and
old rats at surgery were sacrificed 1.5 mo.
the same results were obtained; e.g. in 24-
rats with hepatectomy, the lobes were
ophic as compared to controls, while in
th hepatectomy at the age 10 days, lobe
s similar to that in controls. Larger size
nd more in treated than in controls. Age
ecisive significance in the determination
structure of regenerated liver; structure
organ at the moment of surgery determines
ucture in the process of regeneration.

THE EFFECT OF DIET UPON THE BILIRUBINEMIA
OF THE GUNN RAT. TESTS WITH PERITONEAL
CHOLOSTASIS AND ALSO NOVOBIOCIN IN
TS. (Fr.) Housset, E. (Animal Biol.
h. Res. Unit, Paris), J. P. Etienne, J. P.
P. Oudéa, M. C. Oudéa and P. Manchon.
ol. (Paris) 15(9-10):457-469, 1967.

nn rats (150-400 g), in addition to
n determinations in blood and bile using
l and benzene extraction methods, total
olesterol was measured; alkaline phos-
and 5 nucleotidases were also determined.
ound that the more fat in the diet the
bilirubinemia. On a commercial diet
eral fat content for 7 days 30 rats av.
bilirubinemia; on a diet with 3% fat
ys bilirubinemia was 11.2 mg%; after a
o the fat-rich first diet bilirubinemia
mg%. Control fat-diet tests confirmed
lues. The nature of the fat and the
f saturation did not seem to matter.
of the bile duct and section of the
t with drainage into the peritoneal cavity
thyl-isothiocyanate admin. (100 mg/100 g
body wt.) introduced by gastric intubation, did not affect bilirubinemia of the Gunn rat. The enzyme changes were similar to those in the normal rat under the same experimental conditions. Ultramicroscopic changes were not different from those in the normal rat. Novobiocin i.v. inj. (4 mg/100 g body wt.) into the normal rat causes a sharp fall in the amount of bilirubin excreted in the bile but had no effect on bilirubin excretion in the Gunn rat.

9860 EARLY HISTOCHEMICAL CHANGES IN THE LIVER OF YOUNG RATS IN PROTEIN-CHOLINE INSUFFICIENCY. (Rus.) Gupalo, E. E. Inst. Ther., Moscow). Arkh. Pat. 29(3):53-58, 1967.

A total of 40 immature male rats were maintained on a choline-free low-protein diet for up to 30 days; on day 2 of the diet, they exhibited redistribution of enzyme activity from periportal zones of the hepatic lobe into its central portions in connection with the development of periportal adiposis. From the start of the diet and up to 30 days on the diet, synthesis of fats, fatty acids and phospholipids in liver cells was stimulated; this was accompanied by depression of all other enzymatic systems studied. Droplets of fat were observed after 1-2 days of the diet; their content increased and by day 30 the formation of fatty cysts was observed. Phospholipids, usually not found in the normal liver, appeared after 2 days, reached their max. by 6-8 days and decreased by day 30. Glycogen content gradually decreased from the second-sixth day, and its content varied in different zones; by the thirtieth day it was markedly decreased and uniform throughout the lobe. Activity of acid phosphatase after 2 days was higher in the central and middle part of the lobe, and lower on the periphery (at normal, the highest activity was found in this portion); by day 8 its activity was reduced and evenly distributed in the central and peripheral portions, and by the thirtieth day the amount of this enzyme was markedly decreased and diffusely spread in the lobe, with no even distribution of activity. Alkaline phosphatase was found in small amounts in the normal state, and by the second day had almost completely disappeared from the periportal zone and appeared in the region of the central vein and its endothelium; in the case of fatty cyst formation, it continued to accumulate, chiefly in the pericentral zones. Cytochrome oxidase was markedly decreased in the first days of the dietary regimen. Succinic dehydrogenase was redistributed, with subsequent gradual and uniform decrease of enzyme activity. After 2 days, the region of max. activity of nonspecific esterase decreased, but its content increased; subsequently the amount of this enzyme also decreased around the central veins.

9861 EFFECT OF ETHANOL ON HEPATIC METABOLISM OF SULFOBROMOPHTHALEIN. (E.)

Lieberman, A. H. (U. California Sch. Med., San Francisco) and A. W. Childs. Amer. J. Physiol. 213(2):353-357, 1967.

Hepatic uptake, storage, conjugation and excretion of BSP (2 mg/100 g; admin. i.v.) were determined in rats. Conjugated BSP in bile or extract of liver was identified by a method using paper chromatography. Ethanol, admin. i.p. in a dose of 120 mg/100 g, caused a decrease in the proportion of conjugated BSP in storage and in the rate of excretion of conjugated BSP in bile, but did not affect the rate of uptake, excretion of unconjugated BSP or the ability of the liver to excrete admin. BSP-glutathione mercaptide. It is concluded that ethanol decreases the rate of excretion of BSP by impairing conjugation with glutathione. Hepatic cellular mechanisms for uptake of dye from plasma and transfer of dye from cell to bile are independent of the mechanism for conjugation, and conjugation is a rate-determining step in the excretion of BSP.

9862 THE EFFECT OF PHENOBARBITAL ON HYPERBILIRUBINEMIA IN GLUCURONYL TRANSFERASE DEFICIENT RATS. (E.) DeLeon, A. (Albert Einstein Coll. Med., New York, N. Y.), L. M. Gartner and I. M. Arias. J. Lab. Clin. Med. 70(2):273-278, 1967.

Homozygous, glucuronyl-transferase-deficient rats (Gunn) were given daily s.c. inj. of sodium phenobarbital for 12 wk. in increasing dosages from 60-200 mg/kg. This treatment increased the ratio of liver wt./total body wt. and produced a 2.5-fold increase in side-chain oxidation of hexobarbital in vitro as well as an abundance of smooth endoplasmic reticulum, as observed cytochemically and by electron microscopy. Drug treatment did not reduce serum unconjugated bilirubin conc., increase serum direct-reacting bilirubin conc., result in the appearance of bilirubin glucuronide in the cannulated bile duct or increase hepatic glucuronyl transferase activity in vitro; however, daily admin. of 80 mg/kg of sodium phenobarbital for 14 days to normal Sprague-Dawley rats significantly increased hepatic glucuronyl transferase activity in vitro, with bilirubin as a glucuronide receptor. It is suggested that the Gunn rat is genetically incapable of forming bilirubin glucuronide, whereas some humans with jaundice of this type have a relative deficiency of glucuronyl transferase and may respond to phenobarbital. The response to phenobarbital may provide a means for studying the expressivity of this inherited defect.

9863 ESTIMATION OF HEPATIC IRON STORES BY IN VIVO MEASUREMENT OF MAGNETIC SUSCEPTIBILITY. (E.) Bauman, J. H. (Western Reserve U. Sch. Med., Cleveland, Ohio) and J. W. Harris. J. Lab. Clin. Med. 70(2):246-257, 1967.

The positive magnetic susceptibility of hemosiderin and ferritin, a property very unusual to biological materials, suggested that this characteristi
could be exploited for estimating hepatic st
Fe. Calculations indicated that each g of f
ritin-hemosiderin (storage Fe) would be expe
to increase the magnetic susceptibility of a
liver by approx. +0.08 x 10^{-6} electromagneti
U/cm^3. Using an instrument devised to make
in vivo and in vitro measurements of magneti
susceptibility, satisfactory agreement with
above predicted value was obtained by in vit
measurements of rabbit livers containing dif
ferent but known amounts of storage Fe. In
rats linear body scans of magnetic susceptib
were repeatedly made during progressive Fe l
ing, and proved capable of detecting hepatic
overload. The conc. of hepatic storage Fe t
could be detected by these means was signifi
less than the av. reported in livers of pati
with hemochromatosis. It is probable that h
Fe stores in the human can also be safely ev
by magnetic susceptibility measurements usir
similar, but suitably modified, externally a
sensing device.

9864 EFFECT OF BILE SALT AND SECRETIN
BILE FLOW FROM THE ISOLATED PERFU
PIG LIVER. (E.) Hardison, W. G. (Boston C
Hosp., Mass.) and J. C. Norman. Gastroente
53(3):412-417, 1967.

The effects of 2 choleretic agents, secreti
cholic acid, upon the isolated perfused pig
were studied; the actions of these substanc
upon the perfused liver were similar to the
known actions in vivo. Cholic acid caused
creased flow of bile rich in bile salt with
major changes in relative Cl and bicarbonat
secretin stimulated the flow of bile rich i
bicarbonate, but poor in Cl. The similarit
tween these effects and the known effects o
secretin and bile salts in vivo suggests th
perfused liver performs its function of bil
formation in a physiological manner (this i
portant when the use of the perfused pig li
support patients with hepatic failure is co
sidered). Since the perfused liver is isol
from endogenous regulators of bile flow, it
advantages over the intact bile fistula ani
as a preparation to study bile regulatory
mechanisms. In addition, since varying amo
of bile salts and possibly circulating secr
are presented to the pig liver during perfu
of patients with hepatic failure, bile flow
much of its usefulness as a quantitative me
of liver function during clinical perfusion

9865 STUDIES IN THE BIOSYNTHESIS OF HE
AND BILIARY LECITHINS. (E.) Bal
J. A. (Albany Med. Coll., N. Y.), D. A. Bee
D. H. Treble and H. L. Spitzer. J. Lipid R
8(5):486-493, 1967.

Male rats with biliary cannulae were inj. w
linoleate-1-^{14}C, stearate-1-^{14}C, palmitate-
L-methionine-methyl-^{14}C, phosphate-^{32}P and
methyl-^{3}H in various combinations and the i
corporation of these isotopes into the phos
lipids of plasma, liver and bile was determ

hr. Linoleoyl lecithin of liver attained
specific activity with respect to phos-
^{2}P and choline-methyl-^{3}H than did arachido-
cithin. Lecithin in bile attained higher
activities with respect to phosphate-^{32}P,
-methyl-^{3}H and linoleate-1-^{14}C than the
onding hepatic lecithins. Stearate-1-^{14}C
nitate-9-10-^{3}H attained highest specific
ies in the hepatic lecithin fraction rich
idonic acid. The specific activity of
phosphatidyl ethanolamine was lower with
to saturated fatty acids, but much higher
spect to ^{32}P than any lecithin. The ratio
fic activity of ^{3}H in methyl groups from
to ^{14}C in methyl groups from methionine
ic sphingomyelin was lower than in hepatic
l lecithin. These results favor the
is that 1) exchange of saturated fatty
ays a role in the formation of lecithins;
the unsaturated fatty acids do not undergo
ant exchange and determine the pathway of
esis of lecithins; and 3) that there is
ore than 1 pool of cytidine 5'-diphosphate-
in liver or a pathway of biosynthesis of
from choline not involving cytidine
sphate-choline as an intermediate.

ELECTRON MICROSCOPIC AND BIOCHEMICAL
STUDY OF LIPOPROTEIN SYNTHESIS IN THE
PERFUSED RAT LIVER. (E.) Jones, A. L.
Med. Sch., Boston, Mass.), N. B. Ruderman
. Herrera. J. Lipid Res. 8(5):429-446,

ated perfused rat liver was used to study

ly been described in the liver cell Golgi
s, smooth endoplasmic reticulum and space
When the perfusion medium was enriched
oleate, the number and electron opacity
particles increased markedly. Sequential
showed that they appeared first in the
urfaced terminal ends of the rough retic-
e smooth endoplasmic reticulum proper, and
i apparatus and later in the space of
After 60 min. of perfusion, particles of
size and shape as those in the liver
uld be isolated in large numbers from
less than 1.006 fraction of the perfusate.
livers perfused with an identical medium
out linoleate did not show these changes.
markedly depressed the production of
Å particles by livers perfused with an
ich medium; however, it did not interfere
formation of large cytoplasmic droplets
al fat. In keeping with these findings,
blocked the incorporation of oleate-^{14}C
oprotein triglyceride isolated from the
e, but did not interfere with the appear-
the labeled fatty acid in tissue tri-
e. Puromycin also blocked incorporation
ne-^{3}H into both tissue protein and per-
ipoprotein. It is concluded that the
Å particles observed were, probably,
density lipoproteins and that their
is blocked by puromycin, presumably
through interference with the synthesis of their apoprotein.

9867 BILIRUBIN GLUCURONIDE FORMATION IN DEVELOPING GUINEA PIG LIVER. (E.) Flodgaard, H. J. (U. Copenhagen, Denmark) and R. Brodersen. Scand. J. Clin. Lab. Invest. 19(2): 149-155, 1967.

The formation of bilirubin diglucuronide by guinea pig liver tissue slices and microsomes was studied, using a radioisotope derivative method for the quantitative determinations, at various stages of perinatal development. Incubation of bilirubin with microsomes was performed in 2 ml vol. containing 14 mM $NaHCO_3$, 62 mM NaCl, 0.6 mM KH_2PO_4, 10 mM glucose (phosphate-bicarbonate soln.), bovine albumin, 30 g/liter, uridine-5-diphosphate glucuronic acid ammonium salt and bilirubin. o-Aminophenol was incubated in the same medium as was used for bilirubin. o-Aminophenol inhibited the conjugation of bilirubin competitively and *vice versa*; from the K_m and K_i values, it was concluded that bilirubin and o-aminophenol are conjugated by 2 different enzymes. The liver slices rapidly lost uridine-5-diphosphate glucuronic acid to the medium, and the rate of bilirubin conjugation decreased; from the course of these processes, an approximate value of the K_m for uridine-5-phosphate glucuronic acid was calculated. Uridine-5-diphosphate glucuronic acid conc. in the guinea pig liver was found to increase approx. 20-fold during development from 1 mo. before birth to 4-5 days of age, when adult values were reached. The possible role of the low uridine-5-diphosphate glucuronic acid content of the liver of the fetus and newborn in the pathogenesis of neonatal jaundice is discussed.

9868 ISOLATED DOUBLE PERFUSION OF THE LIVER IN THE STUDY OF THE RETICULO-ENDOTHELIAL SYSTEM. (E.) Jeunet, F. S. (U. Minnesota, Minneapolis), W. J. Shoemaker and R. A. Good. Nature (London) 215(5096):61-62, 1967.

A single perfusion apparatus was modified so that a single isolated liver could have its entire perfusate changed without interrupting circulation through the liver, thereby forming a double perfusion apparatus. The liver was isolated from a Sprague-Dawley rat and perfused with a soln. which was a mixture of total fresh blood taken from rats of the same strain and heparinized (500 U/ml) with Tyrode soln. (pH 7.4-7.6) in the ratio of 3:1; 20 mg chlortetracycline and 800 mg of dextrose was added, and total vol. of the perfusate was 100 ml. Flow through the liver was kept constant at 15 ± 1 ml/min. Radioactive "Aurcoloid" containing ^{198}Au was used to measure the speed of clearance by the liver. When 2.5 mg "Aurcoloid" was added 3 min. after beginning perfusion, 50% of the Au was cleared from the perfusate 10 min. later; the same dose was added at 40 min.; 50% clearance took 14 min., and after the third dose, time required for 50% clearance was 23 min. When the entire perfusate was changed at 155 min., using rat blood fresh to the liver, and another similar dose of "Aurcoloid" added, the time required to clear 50% of the circulating Au was again short, 8 min.; after another dose it was only 14 min., and after a third, 21 min. Diminution of the rate of clearance of Au was increased simply by changing the perfusate for fresh, previously unperfused, rat blood. These findings indicated that rat serum contains a factor that may be exhausted by the initial repeated perfusion of Au, and that the factor was renewed by addition of fresh rat blood to the perfusing system. It is suggested that the decreasing rate of clearance observed initially was due to exhaustion of the serum factor and not to functional blockade of the reticulo-endothelial cells or to a shift in site of phagocytosis. Careful monitoring of the outflow of blood and controlled circulation allowed specific exclusion of outflow circulation block as a basis for decrease in function. Also, variation of the timing of the point of admin. of the colloidal Au after beginning of perfusion indicated clearly that the circulating factor was not being used non-specifically or metabolized by the liver. It is thought that use of this double perfusion system should be valuable in obtaining critical analysis of reticulo-endothelial function in the absence of many factors difficult to control in the intact animal.

9869 UPTAKE OF CHYLOMICRON LIPID BY RAT LIVER PARENCHYMAL CELLS IN VIVO. (E.)

Higgins, J. A. (U. Liverpool, England) and C. Green. Nature (London) 215(5096):83, 1967.

Chylomicrons were obtained after admin. of glycerol tri(1-^{14}C) palmitate to rats in which thoracic duct cannulae had been established; the only heparin used was a small amount in the saline filling the cannula when it was inserted. The washed chylomicrons (0.75-2.05 mg of lipid) were inj. into the exposed femoral vein of fed rats over a 30-sec. period; 1 min. after inj. was completed, the liver was perfused with ice-cold, Ca-free Locke's soln. containing 0.27 M sodium citrate, and homogenized in Hanks soln. The homogenate was filtered through nylon mesh (60 µ pore size) and the filtrate centrifuged at 1300 g for 1 min.; the sedimented parenchymal cells were washed and the total lipid extracted for determination of ^{14}C distribution. Most of the ^{14}C-palmitic acid associated with the hepatic parenchymal cell was found in the triglyceride (73.1 ± 2.4% after chylomicron inj., compared to 93.1% in original chylomicrons), and much smaller amounts were found in phospholipids (19.2 ± 3.0% after chylomicron inj., compared to 6.8% of original chylomicrons). When tritiated palmitic acid was inj. as a complex with albumin, 57.8% of the radioactivity was in the phospholipids and 27.8% in the triglyceride. If chylomicron triglyceride had been hydrolyzed to nonesterified fatty acids before uptake by the liver cells, the distribution of radioactivity should have
been similar in the 2 experiments. Since th
are so different, these results establish th
under normal physiological conditions, chylo
triglycerides are directly removed from the
culation by the liver cells.

9870 DETOXIFICATION OF ENDOTOXIN BY PE
OF LIVER AND SPLEEN. (E.) Rutenl

(Harvard Med. Sch., Boston, Mass.), R. Skar
C. Palmerio and J. Fine. Proc. Soc. Exp. B
Med. 125(2):455-459, 1967.

The mortality of a dose of bacterial endoto
in rabbits, which was 85% when inj. into a
systemic vein, was reduced to 11% when it w
inj. through a mesenteric vein; this indica
that it must traverse the liver before ente
the systemic circulation. Bacterial endoto
(Salmonella enteritidis MLD/80 = 1 mg/kg) i
plasma was perfused through the denervated
spleen in vitro; corresponding dilutions of
fusate and effluent were assayed for detoxi
in pertussis-treated mice, and by the immun
fusion technic. These assays showed substa
detoxification of the endotoxin in the effl
and of the endotoxin retained by the spleen
Since the degree of dilution of the effluen
have been great enough to reduce the endoto
content/aliquot below the sensitivity of th
bioassay technics, partially purified extra
of spleen were also interacted with endotox
detoxification by the same assay technics w
demonstrated. These results showed that th
and spleen not only rapidly extract, but al
rapidly detoxify, bacterial endotoxins. Be
of varying degrees of vasoconstriction of t
circulation to these organs in the normal a
the full detoxifying potential of these org
when challenged may not be available.

9871 ROLE OF THE LIVER IN METABOLISM O
DL-NOREPINEPHRINE-^{14}C. (E.) Haz

C. G. (Mayo Clin., Rochester, Minn.), R. P.
E. V. Flock, S. G. Sheps, A. Schirger and C
Owen, Jr. Amer. J. Physiol. 212(6):1229-12
1967.

When whole blood from male Sprague-Dawley r
was incubated with DL-norepinephrine-7-^{14}C
acetate, 2 µg/100 ml, at 37°C, the mean upt
of ^{14}C into RBC was 32.0% at 15 min., 54.2%
1 hr. and 60.5% at 2 hr. and thereafter, wi
of the remainder being bound to plasma prot
nonselectively, from which it could be remo
readily by alumina at pH 8.4. Following in
6.1-9.8 µg of the compound into the tail ve
intact rats weighing 250-300 g, 74.5% of th
was excreted in the urine within 5 hr. Dur
the first hr., approx. 20% of the total was
creted as unchanged norepinephrine; 33% as
3-methoxy-4-hydroxyphenylglycol sulfate. S
amounts of normetanephrine, 3-methoxy-4-hyd
phenylglycol, 3,4-dihydroxymandelic acid, n
epinephrine glucuronide and normetanephrine
glucuronide were also excreted during the f

During the 4 hr. following, large amounts of
ary ^{14}C were found in normetanephrine gluc-
ide and 3-methoxy-4-hydroxyphenylglycol sul-
; smaller amounts in unchanged norepinephrine
ree normetanephrine. In rats bearing biliary
ulas, 5-hr. urinary excretion of ^{14}C was 71.5%
66.5%, resp., following inj. into the tail
or portal vein, while 5-hr. biliary excretion
10.7% and 22.3%, resp. In both cases, approx.
of the biliary ^{14}C was found in 3-methoxy-4-
oxyphenylglycol sulfate; approx. 40% in
etanephrine glucuronide. In hepatectomized
receiving 4.1-6.5 μg, as above, 5-hr. urinary
etion of ^{14}C was reduced to 32.3% and the
t was poorly tolerated. Radioactive compounds
he urine were distributed as in intact animals.
radioactive bile was collected and infused
the duodenum of intact rats, 11.2% of the
oactivity was excreted in the urine in 5 hr.;
%, in 48 hr. Fecal excretion totaled 22.4%.
isolated rat liver was perfused with blood
aining 0.05-4.0 μg/100 ml, the liver rapidly
red most of the norepinephrine in the plasma
approx. half that contained in the RBC, form-
large amounts of 3-methoxy-4-hydroxyphenyl-
ol sulfate and normetanephrine glucuronide,
were excreted in bile and also added to the
ulating blood, the 2 compounds being maintained
ne same ratio to each other, in both bile and
ulating blood, as that which was found in the
of animals bearing biliary fistulas: e.g.,
resp. Only 7-10% of the total dose of
oactivity was found in hepatic tissues after
of perfusion. Free and conjugated nor-
nephrine accounted for more than 66% of this
ue radioactivity; free and conjugated 3-methoxy-
droxyphenylglycol, for less than 33%. It is
luded that the rat liver plays a major role
nactivating and metabolizing circulating
orepinephrine and excretes only conjugated
bolites into the bile and peripheral circula-
although other tissues, working at a slower
release both free and conjugated metabolites.

SOME METHODICAL REMARKS TO ROUTINE
DETERMINATION OF LIVER DETOXICATING
ION WITH THE HELP OF THE METABOLISM OF
OBENZOIC-^{131}I ACID. (Cz.) Eysselt, M.
yne U., Brno, Czechoslovakia), J. Dohnálek
. Polášková. Vnitrni Lek. 13(1):77-84, 1967.

nts who did not receive food and water for
. preceding the test urinated to empty their
ers and received p.o. 20-25 μc (about 2 mg)
e Na salt of o-iodobenzoic-^{131}I and in 20 ml
0. Subsequently they were allowed to drink
of H_2O/kg wt. but during the next 2 hr. they
not allowed to drink or eat. Thereafter
irst urine samples were collected and the
nts were allowed to drink and eat. The
d and third urine samples were collected 4
hr. after admin. of o-iodobenzoic-^{131}I acid,
If necessary, the urine samples were
fied by acetic acid and all but 1 ml of each
e was used for determination of radioactivity.
ing the radioactivity of the samples against
the time of their collection made it possible to determine the half-life of o-idobenzoic-^{131}I acid excretion. The 1 ml samples of urine were used for analysis of the metabolic products of o-iodobenzoic-^{131}I acid. They were separated by paper electrophoresis in 0.1 M acetate buffer pH 5.5 (Whatman No. 1 paper; 200 volts, separation time 1.45-2.0 hr.; all compounds migrated to the anode) and identified by comparison of their mobility with those of standard labeled compounds applied to the same strip of paper. The individual spots on the dried electrophoretogram were located by scanning for radioactivity, were cut out and their radioactivity determined. Thus, the proportion of o-iodobenzoic-^{131}I acid to its various metabolic products (o-iodohippuric acid, o-iodobenzoylglucuronic acid, and a third unidentified compound) could be estimated.

9873 CONTROL OF LIVER CELL REPLICATION BY ALBUMIN NEED. (E.) Sudweeks, A. D. (U. Colorado Sch. Med., Denver) and R. B. Hill, Jr. J. Cell Biol. 34(1):404-406, 1967.

Adult female white rats were divided into experimental and control groups; in both, a third of the calculated circulating blood vol., calculated as 50 ml/kg, was removed. In controls, the whole blood was returned immediately; in the experimental group, it was replaced immediately with an equal vol. of fresh RBC suspended in saline with 10% glucose at a hematocrit equal to that of whole blood. Tritiated thymidine (1 μc/g) was admin. i.p. to each rat at 16, 19 and 22 hr. after plasmapheresis. Samples from all 4 major lobes of the liver of each rat were sectioned and radioautographed, as well as a section from each rat kidney. Each animal had a considerable decrease in circulating albumin as a result of plasmapheresis. In control animals, labeling of nuclei was slightly increased over baseline values, whereas in the livers of experimental animals, the labeled nuclei were increased several-fold. Labeled nuclei were uncommon in kidney, and no increase in labeled nuclei was observed in kidney after plasmapheresis. It is suggested that the rate of production of differentiated products of the liver, e.g., albumin, is controlled largely by the number of synthesizing cells, and that in order to increase markedly the hepatic synthesis of albumin, DNA synthesis and cell division must first occur. In addition, an hypothesis is proposed that distribution of functions among hepatocytes may be partially controlled during DNA synthesis or mitosis.

9874 THE PROBLEMS OF CIRCADIAN RHYTHM OF MITOTIC DIVISION OF LIVER CELLS IN ADULT RATS. (Cz.) Magrot, T. (Charles U., Plzen, Czechoslovakia) and F. Fakan. Plzensky Lek. Sborn. 27:41-52, 1966.

Changes in the mitotic index, in the content of DNA and RNA, and in the level of succinic dehydrogenase occurring within 1 day in rat liver tissue were determined as were the levels of blood glucose. Male Wistar rats (44) were fed 4 wk. before and during the experiment only once a day (between 6 and 7 p.m.) with Larsen's diet. Groups of 5-6 rats were killed in 3-hr. intervals and their livers and blood collected. The highest number of mitoses was observed in liver tissue harvested at 1 p.m. (4.2/6000 hepatocytes) and the lowest at 10 p.m. (0.16). However, the differences between various groups were statistically insignificant. The curve characterizing the variation in the DNA content of the liver tissue showed a sharp peak at 7 a.m. and a minimum between 7 p.m. and 1 a.m.; the differences (about 1.5 fold) between these groups were statistically significant. This was paralleled by a similar variation in the RNA content, although the peak observed at 7 a.m. was not as pronounced as with DNA. No correlation was found between the nucleic acid content and the mitotic index of liver tissue of individual animals. The highest level of succinic dehydrogenase in the liver was found at 7 p.m., e.g. immediately after feeding; thereafter, the level of the enzymes gradually decreased reaching a minimum (about 33% of the max. value) at 10 a.m. A correlation was found between the variation of the DNA content and that of succinic dehydrogenase. The higher the DNA conc., the lower was the level of the enzyme. The conc. of glucose in the blood varied between 90-140 mg%. The differences between the blood samples collected at various times were statistically insignificant.

9875 DAILY RHYTHMIC CHANGES IN TYROSINE TRANSAMINASE ACTIVITY OF THE RAT LIVER. (E.) Wurtman, R. J. (Massachusetts Inst. Techn., Cambridge) and J. Axelrod. Proc. Nat. Acad. Sci. USA 57(6):1594-1598, 1967.

The activity of tyrosine transaminase in the rat liver varies each day over a fourfold range. Such activity is lowest at the start of the light period, rises sharply for 6 hr. beginning several hr. before the onset of darkness, after which it again declines, reaching its lowest level. This rhythm shows a remarkable degree of synchrony in animals kept under comparable environmental conditions. In intact rats the phase relationships of the tyrosine transaminase rhythm appear to be related to the adrenocortical rhythm although hypophysectomized rats still exhibit the basic rhythm as do animals actually deprived of the adrenal gland. This phenomenon suggests the possibility that the 24-hr. cycle in the ingestion of food could produce the rhythm, as could cyclic alterations of pineal function. It is also possible that the rhythm is intrinsic to the hepatic cells themselves. Sprague-Dawley female rats (100-200 g wt.) were subjected to a light-dark cycle. Some animals were kept intact, others were hypophysectomized or adrenalectomized. All rats were exposed to 50-70 ft-candle lighting (lights on for 12 hr. daily, starting at 6, 7 or 8 a.m.) in clear plastic cages for 7-10 days. Food and water were provided at liberty. The activity of tyrosine transaminase varied markedly during each 24-hr. period. Soon after the onse of darkness, enzyme activity was 4 times greate than during the early period of exposure to lig The rhythm persisted even after hypophysectomy or bilateral adrenalectomy, but appeared to be entrained by the adrenocortical secretory cycle in the intact animal.

9876 INCREASED CONVERSION OF URIDINE-5'-PHOSPHATE AND URIDINE-5'-TRIPHOSPHATE TO CYTOSINE NUCLEOTIDES BY A LIVER FRACTION FRO COLCHICINE-TREATED RATS. (E.) Weinfeld, H. (Roswell Park Mem. Inst., Buffalo, N. Y.) and A. A. Sandberg. Biochem. Pharmacol. 16(2):375-383, 1967.

9935 BOWEL ANASTOMOSIS BY INVERTING AND EVERTING TECHNIQUES. AN EXPERIMENTAL STUDY. (E.) Healey, J. E., Jr. (U. Texas, Austin), C. M. Mc Bride and H. S. Gallager. J. Surg. Res. 7(7):299-304, 1967.

Whether coapting the peritoneal layer of the bowel (serosa to serosa), as compared to other methods of intestinal repair, gives the best intestinal healing was investigated. Adult mongrel dogs were fasted for 24 hr., given an enema, and were divided into 4 groups roughly equal in size prior to surgery. At surgery each of the groups received a different type of intestinal closing: inversion, submucosal apposition, eversion (sutured), and eversion (nonsutured). A group of small and large intestinal anastomoses was used as a control. Postoperatively, penicillin (200,000 U) and streptomycin (1 g) were admin. daily for 5 days. Primary healing was seen in all groups and the reaction was histologically similar whether the anastomosis was by inversion, submucosal apposition or by the eversion technics. In those animals in which the intestinal anastomoses were everted, the mortality was markedly low, probably because the intestinal lumen is not narrowed at the anastomotic site (as it is with coapting the peritoneal layer). The results of the present study indicate the Halsted's principle of including the submucosal layer, the strongest layer of the intestinal wall, in the intestinal closure is more practical in facilitation of intestinal healing than is Lembert's recommendation of serosa-to-serosa approximation.

9936 DOUBLE AND TRIPLE CONTRAST TECHNICS IN EXAMINATION OF THE UPPER GASTROINTESTINAL TRACT IN PROBLEM CASES. (E.) Buonocore, E. (U. Tennessee Mem. Res. Ctr. Hosp., Knoxville) and C. H. Brown. Amer. J. Dig. Dis. 12(9):867-877, 1967.

A total of 52 patients with suggestive but inconclusive abnormalities on standard X-ray examinations and/or clinical suspicion of gastrointestinal disease were examined using Ba spray; pneumoperitoneum was induced in 19 of these patients. Double- and triple-contrast views of the gastrointestinal mucosa and gastric wall were produced. Evaluation of distensibility and measurement of gastric-wall thickness improved the diagnostic accuracy in these patients. In all, 32 patients were considered normal in spite of suspicious clinical or roentgenographic findings; in 1 patient, a gastric ulcer escaped detection. In 19 patients the Ba spray technic with pneumoperitoneum confirmed abnormalities suggested, but not conclusively shown, on routine Ba-swallow studies; pathologic conditions found were gastric carcinomas in 7 (infiltrative in 6 and polypoid in 1), tumor infiltration of the medial segment of the gastric fundus from a carcinoma of the pancreas in 1, gastric and esophageal varices in 7, gastritis in 2 and benign gastric ulcer in 2. In 17 of these patients, the diagnosis was confirmed by surgery; in the remaining 2 patients, gastric ulcers wer diagnosed, and although the diagnoses were not surgically proved, the subsequent clinical courses tended to confirm the diagnosis. Tripl contrast views of the gastric wall revealed infiltrating malignancies from primary and metastatic tumors that were not appreciated by standard X-ray studies.

9937 FIELD TRIALS OF THIABENDAZOLE AS AN OVICIDE IN THE CONTROL OF HELMINTH INFECTIONS. III. EPIDEMIOLOGICAL ANALYSIS OF THE EFFECTIVENESS IN THE CONTROL OF Ascaris INFECTION. (Jap.) Kutsumi, H. (Nat. Inst. Health, Tokyo), T. Hara and K. Yamamoto. Nippo Kiseichu Gakkai (Jap. J. Parasit.) 16(1):15-27,

The effect of thiabendazole on Ascaris infectio in a village was studied, according to the rate of new infection among inhabitants in treated and nontreated areas. The ovicide was applied once a mo. at a conc. of approx. 10 parts per million; stool examination was performed on inhabitants every 4 mo. Mass treatment with anthelminthics was carried out in the treated area A (246 inhabitants) and nontreated (329 inhabitants) areas; no mass treatment with anthelminthics was carried out in treated area (157 inhabitants), in order to examine the sole effectiveness of nightsoil treatment. The incidence rates of ascaris infection in the initial and final examinations were 19.9% and 11.0%, resp., in the treated A area; 33.1% and 21.0% in the treated area B; and 14.9% and 11.6 in the non-treated areas. The rate of newly-infected cases was 22.0% and 23.5% in the treat A and B areas, resp. In the nontreated area, however, the rate of newly-infected cases was 21.6%, even in such a low incidence rate as 14.9%. In the nontreated area, fertilized ascaris eggs were observed in 48.8% (20 of 41) the newly-infected cases; in contrast, fertiliz eggs were observed in 10.7% (3 of 28) and 11.1% (2 of 18) of the newly-infected cases in the treated A and B areas, resp. The difference of the rate between the treated and non-treated areas was significant. In treated areas A and B, the increase in number of eggs in feces was noted in 4.8% (1 of 21) and 6.4% (2 of 31), res of the individuals. In the nontreated area, th increase was in 25.8% (8 of 31); this was significantly higher than that in the treated areas. The number of families from which more than 2 newly-infected cases appeared was 5 (19 newly-infected cases) in the nontreated area. However, in both treated areas the number of families mentioned above was low, being 1 (4 cases) in the treated area A and 1 (3 cases) in the treated area B. It is significant that the preventive effect observed in the treated B are in which no anthelminthics was used, was approx the same as that in treated area A.

38 A NEW MODIFICATION OF THE FLUORESCEIN STRING TEST FOR RAPID LOCALIZATION OF
PER GASTROINTESTINAL BLEEDINGS. (E.)
ltonen, E. J. (Malmi Hosp., Helsinki).
stroenterologia (Basel) 107(4):216-222, 1967.

is modified method involves the use of a thin
rforated polyvinyl plastic stomach tube
30 cm long) with a cotton tape and a radiopaque
lament inside. No Hg wt. is employed. After
istening the tube with water, the tube is
aced in the patient's stomach by pushing the
be through the nose and down the esophagus. In
e stomach, the tube is roentgenographically
cated and controlled. The tube is allowed to
ss to the ligament of Treitz. Fluorescein is
en inj. and the tube is removed after 5-10 min.
r purposes of identifying gross blood and
uorescence under UV light. The test takes
prox. 1 hr. and does not depend on the patient's
pacity to swallow. The modification is as
liable as the older, slower method in diagnos-
g cases of profuse, diffuse bleeding and in
ses of gastric bleeding with a negative radio-
gic picture. In patients who manifest a
scontinuous pattern of bleeding from the upper
strointestinal tract, but who have a distinct
eeding site, this modification may result in
me instances of false negative results.

39 PERITONEAL HYPOTHERMIA: PHYSIOLOGY AND INDICATIONS. (E.) Little, J. M.
. Sydney, Australia) and A. H. Goodman.
rgery 62(2):346-351, 1967.

e results of experimental and clinical studies
peritoneal hypothermia are described. The
lanchnic area is an effective heat-exchanger
r the induction of moderate whole-body hypo-
ermia; irrigation of the splanchnic area with
ysiological soln. (isotonic saline or Ringer's
oln.) at 1-4°C produces esophageal temperatures
approx. 30°C in about 45 min. in man. A
mperature gradient develops between the
sophageal core temperature (which closely
arallels aortic temperature) and hepatic
emperature, and hepatic temperatures of 30-32°C
re reached within 20 min., allowing extended
ontrol of hepatic vascular inflow. In external
ooling, no such gradient is produced and the
epatic temperature closely follows the esopha-
eal temperature. Hepatic vascular inflow in
ogs varies with esophageal temperature, as does
ardiac output, and is not clearly related to
epatic temperature. The relation to esophageal
emperature is linear within the temperature range
o 30°C. This type of cooling is chiefly
pplicable to the unprepared patient, in whom an
ndication for hypothermia is found at laparotomy.
hile peritoneal hypothermia is not recommended
or routine use, its safety and efficacy have
een established.

40 ROENTGENOGRAPHIC EVALUATION OF EXPERIMENTAL INTRAPERITONEAL ABSCESS. (E.)
Deysine, M. (Cornell U. Med. Coll., New York, N. Y.), D. Alonso, R. Robinson and F. J. Veith. Arch. Surg. (Chicago) 95(2):220-223, 1967.

A method to produce circumscribed i.p. abscesses in the rat with low morbidity and mortality is described. A total of 50 g of fresh rat feces were mixed with 10 g of $BaSO_4$ powder and 10 ml of isotonic saline; this was placed into gelatin capsules. Control capsules were filled with a mixture of equal parts of $BaSO_4$ and isotonic saline. Capsules (control or experimental) were inserted into the abdominal cavity of male Sprague-Dawley rats by a midline laparotomy in the pelvis. Experimental and control groups consisted of 25 animals each. Roentgenograms of representative animals from each group were taken every 2 days, and a representative animal from each group was sacrificed every 2 days, and its abdomen studied grossly and microscopically. Four of 25 rats in the experimental group died within 36 hr. of operation; autopsy of these showed a disseminated suppurative peritonitis. All control animals survived the procedure and no animals died after the first 36 hr. X-ray examination of experimental animals after 2 days revealed a radiopaque mass surrounded by intestinal loops in the area of capsule insertion; subsequent films revealed development of a radiopaque shell in the area of the abscess wall. This surrounded a lucent area which represented the abscess cavity and purulent exudate. X-rays of controls showed a small pellet of Ba which did not change in shape during subsequent serial examination. This method should be of value in studies of new diagnostic methods for i.p. sepsis. The incorporation of $BaSO_4$ in material inducing abscess allows for radiological visualization of the development and evolution of the abscess wall and can be evaluated periodically without laparotomy.

9941 EVALUATION OF RELIABILITY OF SPLENOPORTOGRAPHIC EVIDENCES OF INOPERABILITY IN PATIENTS WITH TUMORS OF THE EPIGASTRIC REGION. (Rus.) Plotkin, V. I. (Novokuznetsk Inst. Postgrad. Med., USSR) and A. D. Sevast'ianova. Vestn. Khir. Grekov 98(4):70-75, 1967.

In 39 patients splenographic data were compared to findings at surgery. Calculations were made by the method of E. V. Gubler *et al*. wherein each of 8 symptoms found in the splenoportograms were weighted at values between -30 and 100 U; the highest sum of symptom values in the operable group was +25 and in the inoperable group, -5 to +200. In the inoperable group a sum of values near the range of operable patients (up to +25) was found in 9 (32%). The range of operability is equal to triple the amount of the highest sum of values in operable patients, -75 U. This amount approx. correlates to the sum of triple the root mean-square deviation and mean deviation of symptoms in the variable number of operable patients. At high determination of operability ranges in 50-60% of the patients by quantiative analyses of splenoportographic symptoms it is possible to determine operability ranges with sufficient accuracy. To evaluate each symptom it is necessary to consider the character of the process and its localization. In the malignant process if the phlebogram showed vascular amputation (-30 U), especially in combination with collateral circulation, surgery is not indicated. If the character of the process is obscure or benign, surgery should be undertaken. Determination of a filling defect, of decrease in contrast of vascular parts, especially in combination with other signs, could be contraindicative for surgery. A change in the portal vein, independent of primary tumor location, indicated impossibility of radical surgery. Radical surgery is possible in the presence of a filling defect or slight stenosis of the lineal vein and tumor location in the gastric cardia or in the region of the pancreatic tail. With the primary tumor location in the antrum or pancreatic head these changes indicate tumor spread beyond regional lymphatic nodes and surgery is contraindicated. Three case histories are given in detail.

GASTROINTESTINAL DISEASES

GENERAL

A STUDY OF ANTITOXIC IMMUNITY IN
CHILDREN SUFFERING FROM COLIENTERITIS.
) Speranskii, N. P. (Leningrad Sci. Res.
Infect. Dis., USSR). Vop. Okhr. Materin.
11(9):30-34, 1966.

olihemolysin content in blood sera was studied
3 children (age 0- more than 2 yr.) with dif-
t forms of colienteritis (mild form in 118,
ately severe in 59, severe in 46), e.g.,
0111 (144 children) and Strain 026 (79 chil-
. Eighty-three children (age 6 mo.- more
2 yr.) who were carriers of enteropathogenic
richia coli 0111 (44) and serotype 026 (39)
studied. Healthy persons (33 newborns, 36
ren; 0- more than 2 yr., and 33 mothers)
d as controls. In the newborn controls anti-
emolysin was absent; in the children its
nce was determined in 63.6%, usually in titers
-1/80); in adults anticolihemolysin was found
.7% and its titer was higher than in chil-
At the beginning of disease anticoli-
ysin was present in 54 of 118 children with
form (1/20-1/160 titer), in 13 of 59 with
ately severe form (1/20-1/80), in 4 of 46
severe form (1/40-1/80) and in 52 of 83 car-
from the moment of hospitalization (1/20-
). The presence of anticolihemolysin in the
seems to protect children from colienteritis
nditions its more mild course; e.g. 26 chil-
with anticolihemolysin present in the blood
ter 1/80-1/160 showed no pronounced clinical
re or new infection with E. coli, while 20
ren with anticolihemolysin in low titers or
ut anticolihemolysin in the blood, the
cal picture was more pronounced or new in-
on occurred. An increase in anticolihemolysin
nt in the blood was found in 22 of 106 chil-
with the mild form of disease (1/40-1/160),
of 49 with moderately severe form (1/80-
), in 30 of 39 with severe form (1/80-1/1280)
n 7 of 76 carriers (1/40-1/80). An increase
ticolihemolysin was somewhat more often
with colienteritis type 0111 than type 026.
. accumulation of anticolihemolysin found
een the third to fourth wk. prior to the
t of disease was found in 80% of children.

STUDY OF INTESTINAL CONTENTS FOLLOWING
BILIOPANCREATIC STIMULATION WITH TEST
IN PATIENTS SUBJECTED TO SINGLE IRRADIATION
HE EPIGASTRIUM. (It.) Dalla Palma, L. (U.
ence, Italy), M. Cappellini, L. Taddei and
ecciolini. Nunt. Radiol. 32(9):855-881, 1967.

ttempt to clarify the pathogenesis of acute
y sickness, the effects of a single irradia-
of the epigastrium on duodenal contents and
opancreatic secretion were studied in 8 pa-
ts. Duodenal contents were collected im-
ately following admin. of test meal (2.5 g
olyethyleneglycol) and at 10-min. intervals
ng the first hr. and 15-min. intervals during
second hr. on the day before and on the day
of irradiation of the epigastrium (150 r of telecobalt through a field measuring 10 x 15 cm). Control studies were performed in 4 patients on 2 successive days after test meal admin. but without irradiation. The amount of duodenal liquid collected over a 2-hr. period was decreased after irradiation, whereas the amount in controls was increased in half and decreased in the other half. Polyethyleneglycol conc. was decreased in most of the irradiated patients and increased in all but 1 control. All irradiated patients showed a decrease in the amount of polyethyleneglycol collected over 2 hr., whereas 2 of the 4 controls showed a perceptible increase. The conc. of trypsin (with respect to polyethyleneglycol) was increased in irradiated patients and decreased in controls. Likewise, amylase conc. (with respect to polyethyleneglycol) was slightly increased after the test meal in irradiated patients but decreased in controls. Total bile acid conc. (with respect to polyethyleneglycol) was increased after irradiation (increase after 30 min., then decrease up to 90 min., then subsequent increase during the last half hr.) but stablized in controls. Av. pH values were slightly increased in both irradiated and control patients. The various factors (gastric emptying, hormone secretion by the duodenal wall, biliary and pancreatic response to test meal) which make any conclusive interpretations difficult are discussed.

9993 ADENOID CYSTIC CARCINOMA OF THE PAROTID GLAND. (E.) Blanck, C. (Karolinska Hosp., Stockholm), C. M. Eneroth, F. Jacobsson and P. A. Jakobsson. Acta Radiol. [Ther.] (Stockholm) 6(3):177-196, 1967.

A histologic re-examination and reclassification of a series of 1678 parotid tumors revealed that 299 were malignant, and 35 of these (2.1% of the 1678) were adenoid cystic carcinomas. There were 20 women and 15 men; the mean age was considerably lower in men. The age at which the tumor was first discovered ranged from 13-74 yr. (mean, 45.6) and the time of first treatment ranged from 13-79 yr. (mean, 49.3). In 28 cases, there was frank invasion of the salivary gland tissue. Pain was present in 14 (40%) and spontaneous facial paralysis in 10. Ten of the tumors were less than 3 cm in diameter, 15 were 3-5 cm and 7 were more than 5 cm in diameter; the size was not recorded in 3. Tumors were firmly attached in 19, and were mobile in 6. Demarcation was indistinct in 14 and well-defined in 11. In 1 there was dermal ulceration over the tumor. Surgical treatment was mostly conservative, consisting of extirpation in 31, partial parotidectomy in 1 and total parotidectomy in 3. Radiotherapy was given to 34 of 35 patients; it was preoperative in 17, intracavitary in 11 and postoperative in 17. There was local recurrence of the tumor in 21, of whom 17 died. In 14 in which no recurrence occurred, 4 died from the tumor disease and 5 from intercurrent disease.

Metastases occurred in 15, in 3 of whom it was detected on admission and in 12 during follow-up. There were distant metastases in 12, and involvement of the regional lymph nodes in 7. Only 1 patient with distant metastases survived for more than 5 yr. Follow-up was from 5-35 yr.; of 21 who died from the condition, 13 survived at least 10 yr. after appearance of the primary tumor and 4 survived at least 15 yr. The determinate survival rate fell from 73% for cases followed-up for more than 5 yr. as compared to 13% for the 20-yr. follow-up group. Thirteen of 16 with evidence of peri- and/or intraneural growth died, as against only 8 of 19 patients without such growth. Seven of 8 patients with many mitotic figures in the tumor(s) died. It is concluded that the long-term prognosis for this type of tumor is extremely poor, and attention is drawn to the grave significance of spontaneous facial paralysis.

9994 EXTRASALIVARY LYMPHOID ABNORMALITIES IN SJÖGREN'S SYNDROME (RETICULUM CELL SARCOMA, "PSEUDOLYMPHOMA", MACROGLOBULINEMIA).

(E.) Talal, N. (NIH, Bethesda, Md.), L. Sokoloff and W. F. Barth. Amer. J. Med. 43(1):50-65, 1967.

Eight patients who had Sjögren's syndrome from 2-20 yr. presented an array of extrasalivary lymphoid abnormalities to distinguish them, as well as 5 previously reported cases, from others with this syndrome. Lymphadenopathy or other extrasalivary infiltrates were sufficient to arouse clinical suspicion of lymphoma. In all 13 cases, lymphadenopathy was present in 10 and was a presenting complaint in 5. Cervical lymphadenopathy interfered with neck motion and caused cosmetic distress in 2 patients. Splenomegaly and leukopenia were each present in 10 patients. Seven had nonthrombocytopenic purpura, and vasculitis was demonstrated by skin or muscle biopsy in 7 and was probably the cause of peripheral neuropathy in 4. Reynaud's phenomenon and herpes zoster were each present in 4 cases. Salivary gland enlargement was universally observed whereas arthritis was infrequent and not typically rheumatoid. A variably marked infiltration of round cells, associated with atrophy of acinar tissue was present in all the biopsy specimens. Of the 8 case histories presented, 2 had primary macroglobulinemia, 1 had reticulum cell sarcoma and 5 had a syndrome designated as pseudolymphoma (4 of the latter had significant elevations of serum IgM macroglobulins). These data indicate that Sjögren's syndrome predisposes the development of extrasalivary lymphoid abnormalities.

9995 CLINICAL-DIAGNOSTIC VALUE OF DETERMINATION OF THROMBOCYTOPOIESIS IN PATIENTS WITH CANCER OF THE DIGESTIVE TRACT.

(Rus.) Anikin, B. S. (Kuibyshev Med. Inst., USSR). Vrach. Delo (6):18-20, 1967.

Thrombocytograms studied in all 135 patients (83 males, 52 females; age 25-75 yr.) and partial megakaryocytograms in 84 patients with cancer of
the digestive tract [esophagus in 21 (Stages
in 9; 3-4 in 12); stomach in 62 (Stages 1-2 i
3-4 in 42); large intestine in 21 (Stages 1-2
8; 3-4 in 13); rectum in 31 (Stages 1-2 in 14
3-4 in 17)] showed that megakaryocytic growth
bone marrow reacted to the development of mal
tumors. The most pronounced changes of megak
and thrombocytopoiesis occurred in Stages 3-4
especially at tumor localization in the large
testine and rectum; the changes of thrombocyt
and megakaryocytes in cancer occurred in para
manner. Thrombocytograms showed a marked shi
toward old blood platelets, especially pronou
at advanced stages, and a more pronounced inc
in old variability of thrombocytes was noted
tumor location in the lower part of the diges
tract (rectal cancer up to 50-59%); a decrease
the number of mature thrombocytes was more pro
nounced at advanced stages, and immature bloo
platelets, were mostly absent. In Stages 3-4
gastric cancer thrombocytes increased in sing
cases to 826,000-1,010,000/ml. A good functio
ability of blood platelets was noted in a stu
of thrombocytes in native preparations. Megakaryocytograms showed a significant percentag
degenerate cells (anisocytosis, cytoplasmic
vacuolization, nuclear polysegmentation, cellu
fragmentation, and others) especially in advan
stages. Degenerative signs were found in megakaryoblasts and especially in promegakaryocyte
and mature megakaryocytes. The highest numbe
of degenerate megakaryocytes was found in Stag
3-4 of large intestinal and rectal cancer. Th
amount of mature functioning megakaryocytes wa
decreased and thrombocytopoiesis was activated
among megakaryoblasts and promegakaryocytes.
Among some giant cells were found forms with
atypical division. Megakaryocytes were modera
decreased in all locations and stages of the
cancer process, except in single patients with
cancer metastatic to many internal organs, in
whom some increase (up to 250-300/ml) in giant
cells was noted. The changes in thrombocytogr
and megakaryocytograms were observed already i
the patients in Stage 2 of disease, therefore,
together with other clinico-laboratory indices
they could be used for timely diagnosis of mal
nant tumors.

9996 PHYSICAL AND PSYCHOLOGICAL EVALUATIC OF "NON-ORGANIC" ABDOMINAL PAIN. (E

Hill, O. W. (Middlesex Hosp., London) and L.
Blendis. Gut 8(3):221-229, 1967.

A consecutive series of patients, (31, 27 of w
were assessed by a psychiatrist) over the cour
of 1 yr., who complained of abdominal pain for
which no organic cause could be ascertained, w
assessed physically and psychologically. The
majority complained of epigastric pain associa
with distention, nausea without vomiting, loss
wt. or belching. These symptoms, together wit
lack of periodicity in the pain and failure to
obtain relief from food, differed significantl
from a carefully controlled group of patients
with peptic ulcers. When examined psychosocia

number of parents in the entire group of pa-
nts who had themselves suffered from abdominal
n, were significantly in excess to a control
up with organic pain, and many of them died
m this. The patients came from significantly
ger sibships than a control population, and
red high for neuroticism, as estimated by a
sonality inventory (Eysenck inventory). Fre-
ntly, the patients' symptoms began in a setting
bereavement, in some cases with recurrences
similar occasions, or otherwise followed by
e clear upheaval in their lives. Several pa-
nts were considerably depressed when seen, and
atment for depression was followed by disappear-
e of pain. Some seemed to benefit from the
hartic nature of their psychiatric interview.
a further group of patients, their symptoms
her disappeared or were greatly improved by
phenazine or sodium amytal, but not by a placebo.
ee illustrative case reports are given.

7 PRODUCTION OF DIARRHEA IN DOGS PREPARED WITH A GALLBLADDER-COLON FISTULA. (E.)
hambeau, J. O. (Brookhaven Nat. Lab., Upton,
Y.), M. Maetz, J. E. Jesseph and H. J. Brenneis.
h. Surg. (Chicago) 95(2):230-235, 1967.

rteen mixed-breed adult dogs of both sexes
e divided into 5 groups. In Group A, 2 animals
e prepared with an ileocolostomy, to study
effects of increasing conc. of bile salt on
colon. To evaluate the effect of diverting
entire bile secretion into the colon, dogs
Group B_1 were prepared with a gallbladder-colon
tula, with the common bile duct ligated; the
e duct was not ligated in 1 dog (Group B_3;
trol to these animals), and in others, Group C
dogs), it was arranged so that the bile was
erted out of the intestine by forming a gall-
dder-renal pelvis fistula. Nonoperated dogs
Group D served as normal controls. Stools
e arbitrarily classified as formed, mushy and
rrheic. In Group A, admin. of 0-0.5 g of
rocholic acid soln. into the colon produced
change in the type of stool excreted; admin.
1-2 g produced a slight change in the composi-
n of stools passed, and admin. of 3 g or more
ays produced diarrhea. Dogs of Groups B_2, C
D, receiving no taurocholic acid replacement,
reted normal stools. Group B_1 animals receiv-
no taurocholate replacement showed a distinct
nge in the type of stools excreted, with diar-
a predominating. When 0.2-0.4 g of taurocholic
d was admin. p.o., dogs in Groups B_2, C and D
ll had formed stools; the type of stools ex-
ted by dogs in Group B_1 changed from predom-
tely diarrhea to formed. When 1-3 g of tauro-
lic acid replacement was admin. p.o., there
no change in the type of stools excreted in
of the experimental groups. When 4-5 g of
rocholic acid was admin. p.o., dogs of Group B_1
eloped diarrhea; those of Group C showed no
nge in stool types, but those in Groups B_2 and
xcreted more mushy stools. When p.o. tauro-
lic acid was increased to 10 g, the type of
ol passed by Group C and D animals was unchanged; when the p.o. taurocholic acid conc. was increased to 20 g, diarrhea occurred in the controls (Group D). These results document the occurrence of diarrhea after instillation of increasing conc. of bile into the colon; approx. 3 g of taurocholic acid in the colon produced diarrhea. This study also documents the changing pattern of occurrence of diarrhea in nonirradiated animals prepared with a total gallbladder-colon fistula and receiving increasing conc. of p.o. bile salt replacement.

9998 THE PATHOLOGY OF PERITONEAL REPAIR: ITS RELATION TO THE FORMATION OF ADHESIONS. (E.) Hubbard, T. B. (Mercy Hosp., Baltimore, Md.), M. Z. Khan, V. R. Carag, Jr., V. E. Albites and G. M. Hricko. Ann. Surg. 165(6):908-916, 1967.

Peritoneal defects (1.0-6.0 cm in diameter) were created in Wistar rats, albino rabbits and mongrel dogs, and regeneration of the defects was studied; peritoneum regenerated not from the cut edges, but from metamorphosis of in situ mesodermal cells. All portions of a defect healed with equal rapidity, large defects as rapidly as small ones. Laparotomy was carried out on 25 mongrel dogs; in 5 the defects were left open, and in 5 each, they were closed with interrupted 4-0 silk, continuous 4-0 silk, continuous 4-0 plain catgut and continuous 4-0 chromic catgut, resp. Adhesions occurred in 30.1% of open defects, in 72.2% of defects closed with interrupted silk, and up to 90.2% of defects closed with continuous chromic catgut. Defects in parietal peritoneum were created in 60 dogs; on one side of each animal the defect was left open, and on the other side, a similar defect was closed with either interrupted 4-0 silk, continuous 4-0 plain catgut, or continuous 4-0 chromic catgut; open parietal defects resulted in many fewer adhesions than did sutured defects on the opposite side. Sixty open defects produced adhesions in 48.3% of defects; 60 closed defects produced adhesions in 98.3% of defects. This difference was statistically significant in all 3 groups, silk, plain catgut and chromic catgut. A series of cholecystectomies (220), colectomies (130) and hysterectomies (40) were reported in which no peritoneal closure was done giving no demonstrable complications due to this omission. It is concluded that peritoneal defects should not be closed, but should be left open.

9999 CEROID IN THE GASTROINTESTINAL SMOOTH MUSCLE OF THE THAI-LAO ETHNIC GROUP. (E.) Nye, S. W. (Walter Reed Army Inst. Res., Washington, D. C.) and K. Chittayosothorn. Amer. J. Path. 51(2):287-299, 1967.

Ceroid pigment deposits were found in the smooth muscle of the gastrointestinal tract in 105 (75%) of 139 Thai-Lao people of the Korat Plateau region of northeastern Thailand; 64% of the subjects autopsied were males, and the av. age at death was 25 yr., with a range of 1 mo.-70 yr. Pigment was most frequently present in the muscularis mucosae of the esophagus (100% of the affected cases); however, in the immediately adjacent area in the stomach cardia, the muscularis mucosae contained pigment in only 16% of the affected cases. The same type of relationship was found at the pyloroduodenal junction; 58% of the affected cases had pigment in the pyloric muscularis mucosae, but only 18% had pigment in the duodenal muscularis mucosae. The esophageal muscularis propria contained pigment in 37% of the cases, whereas the muscularis propria of the stomach had pigment in 21% of the cases. Also remarkably abrupt was the change in the amount of pigment in the muscularis propria of the stomach at the pylorus, where it was usually difficult to find (10%), and in the muscularis propria of the first portion of the duodenum, where it occurred in 80% of the affected cases. Ceroid was found in the distal duodenum-jejunum-ileum in 75% of the cases, in the colon in 35%, in bladder in 51%, in prostate or seminal vesicle or both in 50%, and in the uterus in 20% of the cases. It was found in the appendix in 49% of the cases, but was usually not heavily pigmented. Ceroid was occasionally found in the thyroid, respiratory epithelium, bronchial smooth muscle, vessels, splenic trabeculae, seminal vesicle epithelium and lymph nodes; in many patients a lipochrome pigment of some type was conspicuous in periadrenal fat. Examination of 48 appendices from patients in central Thailand revealed ceroid in only 2 cases, a markedly lower incidence. Total accumulation of pigment increased gradually with age, and the heaviest deposits were associated with liver disease. These pigment deposits apparently indicate that an antioxidant deficient state existed in the tissues of these people; they are probably indicative of chronic human vitamin E deficiency.

10000 THE ACUTE ABDOMEN IN FEMALE CHILDREN. (E.) Stephens, C. A. (U. Toronto, Canada). Ann. N. Y. Acad. Sci. 142(3):709-717, 1967.

Of 734 girls between 2 and 15 yr. of age with a suspected acute surgical abdomen, 227 (31%) were not operated upon; 507 underwent surgery and no definite diagnosis was made or a nonsurgical condition was found in 120. The main nonsurgical conditions giving rise to an acute surgical abdomen were mesenteric lymphadenitis, acute gastroenteritis, redundant sigmoid syndrome, acute pyelonephritis and pneumonia. In most cases, diagnosis was made on clinical grounds. Acute appendicitis (in 297) was the most common surgical lesion causing abdominal pain; the incidence of perforation was 63% of 297. Gynecological lesions had the highest incidence among those 11-15 yr. old. (10% of 203); a ruptured Graafian follicle was was the most common, then torsion of the ovary, ruptured corpus luteal cyst, torsion of a paraovarian cyst, tubo-ovarian abscess and reflux of menstrual blood. Intestinal obstruction was the cause of acute abdomen in 30 of 507. Between the ages of 2-4 the most common cause was intussusception. A positive diagnosis of peritonitis was made in 23 girls. Gallbladder disease and perforate peptic ulcer accounted for 0.5% of the girls between 2 and 15 yr. old. Trauma was a rare cause seen in only 2 cases. Under the age of 2 (in another study) acute surgical abdomen was due to intestinal obstruction in 90% of the cases.

10001 DIAGNOSTIC PERITONEAL LAVAGE IN ACUTE ABDOMINAL DISEASE: NORMAL FINDINGS AND EVALUATION IN 100 PATIENTS. (E.) Veith, F. J. (Cornell U. Med. Coll., New York, N. Y.), W. B. Webber, R. C. Karl and M. Deysine. Ann. Surg. 166(2):290-295, 1967.

Diagnostic trocar-catheter peritoneal lavages were evaluated in 100 patients with potential acute abdominal disease; diagnoses in these patients included perforated ulcer in 8, appendicit in 11, ruptured spleen or i.p. bleeding in 9, pancreatitis in 10, pelvic inflammatory disease in 6, mesenteric vascular occlusion, intestinal obstruction and other perforations of the gastrointestinal tract in 3 each, miscellaneous inflammatory conditions in 11 and 36 had no acute i.p. disease requiring operation. The fluid was examined for gross appearance, and analyzed for pH, protein, amylase, RBC, WBC and bacteria. Normal ranges of values were defined on the basis of 14 proven and 22 presumptive normal lavages with a trocar, and 10 normal lavages without a trocar. Approx. 50% of the normal lavages were pink or red in color and contained 3200-75,000 RBC/cc^3 of lavage fluid. In these 100 patients, 23 diagnostic lavages were of decisive aid in management of the patients; in 11 a planned but unnecessary operation was avoided and in 12 lavage guided reversal of a previous decision not to operate; lavages in 38 were of minor or confirmatory value. In view of technical modifications and normal values established, only 3 of the lavages were misleading; 2 were falsely positive and 1 was falsely negative. Only 1 lavage was not representative of peritoneal fluid. There were 5 incidental complications (mesenteric laceration in 2, and 1 each of entrance into intestine, laceration of psoas muscle and laceratio of the intestinal wall), but none was detrimental or required therapy. It is concluded that this procedure is indicated and of value in selected patients in whom diagnosis is difficult because of intercurrent medical or surgical problems. This procedure is contraindicated under the following circumstances: 1) when diagnosis can be made with clarity by standard means; 2) when ther are multiple scars and distended intestine; 3) in the differential diagnosis of appendicitis and pelvic inflammatory disease; 4) in the differential diagnosis of an overt localized inflammatory process; and 5) in pregnancy.

10002 PORTAL-SYSTEMIC VENOUS SHUNTS IN HEMORRHAGIC SHOCK IN THE DOG AND MONKEY. (E.) Waldhausen, J. A. (Indiana U. Med. Ctr., Indianapolis), F. L. Abel and W. L. Pearce. Ann. Surg. 166(2):183-189, 1967.

irreversible shock is accompanied by gross congestion in the small intestine of the dog, but not in the small intestine of the primate. In order to study the possible role of portal-systemic shunts as alternate pathways to drain the splanchnic circulation in the monkey, ^{85}Kr (at a conc. of approx. 1.0 mc/ml) and ascorbic acid were inj. into the portal vein. The isotope was monitored by a Geiger-Mueller tube in the expired air; and ascorbic acid was detected by a platinum electrode in the right atrium. Appearance times were sensitive to artificial portal-systemic shunt flows of 5 ml/min. Six dogs and 7 macaque monkeys (3 *Macacus rhesus*, 4 *Macacus nemestrina*) anesthetized with morphine sulfate and pentobarbital-Na were subjected to a standardized hemorrhagic shock procedure; the duration of hemorrhage av. 263 min. (range 158-397) in the dog and 164 min. (range 55-180) in the monkey. In the dog and the monkey, appearance time was shortened by 51.0 ± 8.6% and 62.1 ± 9.1% of control, resp., with reinfusion of the lost blood. When the portal vein was occluded, the appearance time in the dog was either greatly prolonged or the indicator never appeared. In the monkey, with portal vein occlusion, the appearance time became shortened, suggesting portal-systemic shunts. Although both dog and monkey had elevation of the portal pressure with occlusion, this was more pronounced in the dog (monkey: 29.2 ± 1.8 mm Hg; dog: 36.0 ± 1.9 mm Hg). Appearance time of ascorbic acid was always shorter than that of ^{85}Kr. These results suggest that portal-systemic shunts do decompress the portal vein in the monkey during hemorrhagic shock.

10003 FIBRINOLYTIC ACTIVITY OF COLOSTRUM AS A POSSIBLE ACTIVATING FACTOR OF GASTROINTESTINAL BLEEDING IN THE NEWBORN. (It.) Brughera, F. (Provinc. Inst. Child Protection & Assistance, Milan, Italy), P. Salvadori and F. Pellegrino. *Minerva Pediat.* 19(12):537-539, 1967.

The possible use of maternal milk in the treatment of gastrointestinal bleeding (melena) in the newborn is examined, and results are reported in 3 cases. The first infant presented melena at day 2 of life and had already been treated with vitamin K when maternal breast feeding was begun. Although no clinical improvement was observed, the syndrome gradually regressed within 3 days. Thrombocyte, thromboplastin, and residual prothrombin tests were normal. Colostrum differs from milk in its thromboplastin activity. Human plasma was then treated at 37°C with colostrum obtained from a primipara 2 days after parturition. No coagulation resulted, and colostrum appeared to have no thromboplastin activity, probably because of lack of Ca ions. The second infant presented with similar symptoms, but no anticoagulant therapy was admin. After the first 2 bloody stools (positive Abt test), milk from a woman who had given birth 20 days before was admin. (20 ml every 3 hr.). The first stool 8 hr. after treatment was normal in consistency and showed no trace of blood. The Meyer test, however, remained positive for the 6 subsequent stools, but was negative 36 hr. following treatment. Colostrum (20 ml per feeding) was then admin. and a moderately positive Meyer test occurred. With subsequent milk feeding, tests became negative again. In 5 test tubes, 0.7 ml of fibrinogen were added and then transformed into fibrin by the addition of standard thrombin; to each test tube were then added: 0.5 ml of colostrum, maternal milk, meconium, feces suspension from a breast-fed infant, and amniotic liquid, resp. After 80 min. of incubation at 37°, no trace of a coagulum was observed in the test tubes containing colostrum and feces. A third infant presented with melena at day 1. Routine tests were negative and no other signs of bleeding were present. Treatment with milk first, then colostrum, gave results similar to those seen in the second infant, although less marked. Colostrum from the mother when mixed in equal parts with plasma obtained from the child or mother or with control plasma (all with thrombin-induced coagulation) induced complete lysis of the coagulum after 45 min. in plasma samples obtained from the mother and child, but no change in the coagulum of the control sample.

10004 AN ARTERIOGRAPHIC STUDY OF MESENTERIC ARTERIAL DISEASE. I. LARGE VESSEL CHANGES. (E.) Dick, A. P. (Addenbrooke's Hosp., Cambridge, England), R. Graff, D. McC. Gregg, N. Peters and M. Sarner. *Gut* 8(3):206-220, 1967.

The large vessels of the mesenteric arterial system (celiac, superior mesenteric and inferior mesenteric arteries) were examined by lateral lumbar aortography in 100 cases. These were divided into 4 groups, the first 3 including patients without abdominal symptoms in whom aortography was performed for other reasons. These consisted of the following: Group 1, 27 controls, with no evidence of arterial disease, being studied because of abdominal masses, renal lesions, etc.; Group 2, 56 hypertensive patients having renal aortography; Group 3, 12 arteriopathic patients, mostly with intermittent claudication; and Group 4, 5 patients with chronic intestinal ischemia. The types of narrowing observed in this study included 1) ostial (nipping), which may result from a build-up of an atheromatous aortic plaque impinging upon the ostial origin of a mesenteric vessel; 2) plaque formation within the vessel resulting in stenotic narrowing with or without post-stenotic dilatation; 3) irregular stenosis; 4) annular smooth stenoses; and 5) segmental stenoses, which may be unilateral or bilateral. The 2 chief anastomotic developments seen were in the pancreatico-duodenal circuit and in the marginal artery of the colon. The inferior mesenteric artery was not seen at all in 40 patients. A method of estimating the sum of the cross-sectional areas of the celiac, superior and inferior mesenteric arteries is described. A significant difference was found between the means of total cross-sectional areas in the cases with ischemic gut disease and in all other groups, and between that in arteriopathic patients and the controls. There was considerable overlap of individual cases. No case was observed with intestinal ischemia in whom the total cross-sectional area of the main arterial trunks was not reduced to below 66% of normal. There was a significant difference between the amount of aortic atheroma found in controls and all other groups and between the hypertensive group and all other groups, but not between the arteriopathic group and those with probable ischemic intestinal disease. Renal artery abnormalities were found in 22 of 57 patients so-examined; these included stenosis of 1 or both renal arteries in 19, and 1 each of renal cyst, renal neoplasm and horseshoe kidney.

10005 IDIOPATHIC SEGMENTAL INFARCTION OF THE GREATER OMENTUM. CLINICAL AND EXPERIMENTAL CONTRIBUTION TO ITS PATHOGENESIS.

(Sp.) Sosa-Gallardo, C. A. (Cordoba Nat. U., Argentina), L. F. Kesner, A. Ferraris and A. H. Herrero. G.E.N. 21(3):221-246, 1967.

Four patients (a 13-yr.-old boy; 2 women, 1 of whom was 48 yr. old; a 61-yr.-old man) and data obtained from experimental studies on guinea pigs (10), dogs (6), and monkeys (2) were studied. Of 69 cases reported in the literature, venous thrombosis was observed in 20 (29%), while in the remaining 49 (71%) there was either no evidence of thrombosis (48%) or no mention was made of the condition of the veins (23%). Primary venous thrombosis does not seem to be the cause of idiopathic segmental infarction of the greater omentum. In fact, in the present series of 4 cases (3 segmental, 1 total), histopathological studies revealed the presence of signs and cellular elements characteristic of an allergic reaction and, in all cases, cure was obtained by antiallergic therapy (i.v. novocaine, antihistamines, and corticosteroids) without resorting to resection of the omentum. In experimental animals, an allergic reaction similar to that observed in humans was induced by the Arthus-Schwartzman technic using egg albumin and horse serum as antigens. It is concluded that the venous thrombosis observed in some patients with idiopathic segmental infarction of the greater omentum is a consequence and not the cause of infarction. By simple irritation (chemical, toxic, allergic) of the sensory fibers of the autonomic nervous system, characteristic lesions can be produced consisting of active vasodilatation, congestion, edema, hemorrhage, and others.

10006 PREVENTION AND TREATMENT OF EXPERIMENTAL ASCITES SUBSEQUENT TO STENOSIS OF THE INFERIOR VENA CAVA IN DOGS. (A NEW TECHNIC FOR ANASTOMOSIS OF THE THORACIC DUCT AND VENOUS SYSTEM).

(It.) Zotti, E. F. (Civil Hosp., Padua, Italy). Acta Chir. Ital. 22(6):679-692, 1966.

The effects of improved drainage of the thoracic duct in the prevention and treatment of ascites due to stenosis of the inferior vena cava were studied in 30 dogs of 14-16 kg wt. The following operations were performed: simple ligation of the inferior vena cava (Group 1); simultaneous ligation of the inferior vena cava and anastomosi of the thoracic duct and hemiazygos vein (Group 2 10 dogs); ligation of the inferior vena cava with anastomosis performed 7 days after the formation of ascites (Group 3; 6 dogs); only anastomosis of the thoracic duct-azygos vein with special non-suture technic (Group 4; 8 dogs); ligation of the inferior vena cava with anastomosis performed 7 days after ascites formation, using the same non-suture technic as in the previous group (Group 5; 6 dogs). Animals of Group 1 all developed ascites (200-320 ml) within 6-8 days; lymphangiography revealed marked congestion of abdominal and periaortic lymph nodes and thoracic-duct distention. Six dogs of Group 2 were sacrificed 30 days after surgery and no signs of ascites or lymphaticovenous abdominal congestion were present; 2 dogs were kept for a long term as controls and were in good condition at 160 days; anastomosis was pervious in these animals; technic was faulty in 1 dog. In animals of Group 3, ascites disappeared 48-72 hr. after anastomosis; lymphangiography after 1, 7, and 30 days revealed no congestion of abdominal lymph glands, but some venous stasis of abdominal organ was seen. Anastomosis was successful in 5 animal of Group 4, 3 of which were in good condition 124 and 130 days after surgery; 1 dog died from hemo- and chylothorax due to disinsertion of the thorac duct; in 2 dogs who showed signs of clinical complaints, occlusion of the anastomosis occurred before day 30. Anastomosis was pervious in 4 dog of Group 5 30 days after surgery; ascites had disappeared within 48 hr. and an increased flow was observed at the anastomosis site. Results indicate a predominant role of the lymphatic system in the formation of ascites, and further studies are urged with a view to application of the above technic to various clinical conditions (decompensated cardiac congestion and esophageal varice

10007 ELECTRON-MICROSCOPE STUDIES OF EXPERIMENTAL SALMONELLA INFECTION IN THE PRECONDITIONED GUINEA PIG. II. RESPONSE OF THE INTESTINAL MUCOSA TO THE INVASION BY Salmonel typhimurium.

(E.) Takeuchi, A. (Walter Reed Army Med. Ctr., Washington, D. C.) and H. Sprinz. Amer. J. Path. 51(1):137-161, 1967.

Guinea pigs which were preconditioned by 4 days of starvation and then admin. 1 ml of tincture of opium i.p. prior to the admin. by stomach tube of 10 ml of broth which was infected with Salmonella typhimurium usually succumbed within 3 days to a systemic infection with septicemia. The ileum was affected by an acute, diffuse, nonspecific enteritis which was first noted at the 12-hr. stage and progressed in intensity to the 48-hr. stage. The enteritis was characterize by a progressive alteration of the mucosal architecture with a shift in the ratio of the villo to the nonvillous portion of the mucosa. There was blunting, swelling and foreshortening of villi; elongation of the crypt glands and emptyin of goblet cells; increased and abnormal extrusion

epithelial cells (compensated in part by in-
ases mitosis). The bacteria first penetrated
epithelial lining of the intestinal villi and
after a 24-hr. lapse penetrated the lining
the crypt glands. They were rapidly cleared
the intestinal lumen and the epithelial lining,
persisted in the lamina propria and even
iferated within macrophages. These changes
accompanied by a progressive inflammatory
tion of the lamina propria with engorgement
he vessels and an inflammatory cell exudate
ciated with an increased transepithelial mi-
ion of these cells. Vascular changes in the
stinal mucosa became evident and were char-
rized early by intravascular platelet thrombi
later by alterations of the thrombosed vessel
.

8 METHAEMOGLOBINAEMIA AND INFANTILE GASTROENTERITIS.

(E.) Hoh, T. K.
. Hosp., Singapore). J. Singapore Paediat.
8(1):18-23, 1966.

l cases of acquired methemoglobinemia in
nts, and children, 70.5% had gastroenteritis
ients admitted for gastroenteritis comprised
25% of the total admissions). All of these
s developed methemoglobinemia after taking
l Chinese medicinal powders or oil, except
2 cases which had imbibed well water and 4
s of gastroenteritis that were not given any
cation before admission. An additional study
0 cases of gastroenteritis who were not given
medication before admission and whose source
ater supply was not from wells, was performed
etermine the reason for the high incidence
ethemoglobinemia among infants with gastro-
ritis. The initial methemoglobin level in
e patients was higher than the normal value;
was associated with a low level of alkaline
rve in the blood. Daily estimation revealed
, as the level of alkaline reserve rose to
al, the methemoglobin level dropped to a
al level, although no treatment for methemo-
inemia was instituted. Since the methemo-
in was calculated as percent of total hemo-
in and some of the cases were only mildly
drated on admission, it was thought that the
ial high level of methemoglobin in this group
nfants was not related to dehydration and
concentration, but to acidosis. This finding
ests that infants with gastroenteritis, es-
ally those with acidosis, are more susceptible
ethemoglobinemia when given certain medications
that the presence of acidosis favored the
ation of methemoglobin.

IMMUNITY AGAINST EXPERIMENTAL CHOLERA.

(E.) Finkelstein, R. A. (SEATO Med.
Lab., Bangkok) and P. Atthasampunna. Proc.
Exp. Biol. Med. 125(2):465-469, 1967.

ification of the intestinal loop technic
sed for titration of the effect of choleragen
nfection with Vibrio cholerae 569 B Inaba on enterosorption in control and immunized adult rabbits; 5 loops of terminal ileum were made in each animal, with 1-inch segments intervening. Four loops were inoculated with 0.1 ml amounts of dilutions of purified choleragen in saline and 1 loop received 1 ml of 1.0% peptone saline containing 10^8 viable V. cholerae harvested from 6-hr. growth on meat extract agar plates. Skin reactivity to choleragen was assayed in the same groups of rabbits. Immunization was accomplished by parenteral inj. of choleragen in Freund's complete adjuvant; purified choleragen dissolved in sterile physiological saline was mixed with an equal amount of adjuvant so that each 5 ml contained 5 mg of choleragen. Serial dilutions of sera were tested for agglutinins against live vibrios, using infant rabbits. In immunized rabbits, only 2 of 6 animals responded to massive live vibrio challenge, and then to a lesser degree than controls, all of which responded with marked outpouring of fluid into the loops. Immunization also conferred a marked, although not absolute, degree of resistance to intraintestinal challenge with choleragen. Similarly, skin reactivity to intradermal choleragen was markedly decreased in the immunized group, in comparison with simultaneous controls. Neutralization tests showed that each of the postimmunization sera neutralized choleragen, with 1 possible exception. Each of the postimmunization sera had antibodies capable of precipitating choleragen in Ouchterlony tests. All sera from immunized rabbits contained high levels of agglutinins. Parenteral immunization with choleragen actively protected adult rabbits against intestinal challenge with either live vibrios or with choleragen, and a partial degree of immunity to the choleragen may be passively transferred to infant rabbits by means of serum admin. parenterally before challenge.
It is concluded that choleragen offers promise as an effective immunogen against cholera.

10010 ELECTROLYTE REPLACEMENT IN PAEDIATRIC CHOLERA.

(E.) Griffith, L. S. C.
(U.S. Naval Med. Res. Unit No. 2, Taipei, Taiwan),
J. W. Fresh, R. H. Watten and M. P. Villaroman.
Lancet 1(7501):1197-1199, 1967.

Electrolytes were determined in the stools of 58 children with cholera from the Philippines; Group 1 consisted of 19 who were bacteriologically positive for Vibrio cholerae Ogawa (el Tor); and Group 2 consisted of 39 selected from random admissions to the main cholera ward at San Lazaro. Electrolyte losses in the stool were substantially different from those found in adults with cholera. Fecal losses of Na, Cl and bicarbonate were lower, and fecal losses of K were higher, than in adults. Since i.v. soln. for replacement therapy are commonly devised on the basis of adult losses, their use in pediatric cholera provides more Na and Cl than is lost in the child's stool. In addition, such regimens rely too heavily on the p.o. route for admin. of free water (water not containing saline). It is suggested that most of the morbidity and mortality seen in pediatric cholera may be due to over-replacement of Na losses and failure to provide free water i.v.

10089 AMMONIA TOLERANCE IN THE DIAGNOSIS OF ESOPHAGEAL VARICES. A COMPARISON OF ENDOSCOPIC, RADIOLOGIC, AND BIOCHEMICAL TECHNIQUES. (E.) Conn, H. O. (VA Hosp., New Haven, Conn.). J. Lab. Clin. Med. 70(3):442-451, 1967.

The results of ammonia tolerance tests were compared with radiologic and esophagoscopic examinations for esophageal varices in a consecutive group of 275 cirrhotics (262 with Laennec's cirrhosis, 8 with postnecrotic cirrhosis, 4 with hemochromatosis and 1 with biliary cirrhosis; diagnoses were established histologically in all but 5 patients); ammonia tolerance tests were also performed on 24 normal subjects or healthy volunteers, and on 21 patients with fatty infiltration and/or portal fibrosis of the liver which was established histologically. Values of less than 150 μg ammonia N/100 ml were considered to be normal; ammonia tolerance levels greater than 250 μg/100 ml were considered diagnostic of esophageal varices, and values less than 250 were indicative of absence of varices. In the normal controls, ammonia tolerance tests av. 117 ± 13 μg/100 ml, with a range of 88-136; in those with fatty infiltration and/or portal fibrosis of the liver, they av. 120 ± 27 μg/100 ml, with a range of 80-190 μg/100 ml; 3 of these 21 patients had values less than 150 μg/100 ml, and 4 of the 21 had varices as shown by esophagoscopy. In 384 tolerance tests in the cirrhotic subjects, the av. was 243 ± 129 μg/100 ml, with a range of 80-722; 116 of 384 (30%) tolerance tests were normal; in 236 tests (61%), values were less than 250 μg/100 ml, and in 148 tests (39%), values were 250 or over. Esophageal varices were detected by esophagoscopy in 43% of the patients, by radiologic examination in 37%, and on the basis of ammonia tolerance, in 39%. Ammonia tolerance tests agreed with radiologic examinations in 69%, with endoscopic examinations in 70%, and with 77% of the group of patients in whom both esophagoscopic and radiologic interpretations agreed. By comparison, Ba contrast examinations agreed with esophagoscopy in 71%. The magnitude of esophageal varices by esophagoscopy correlated closely with the degree of abnormality of ammonia tolerance. These studies indicate that the ammonia tolerance test is a reliable screening test for the presence or absence of esophageal varices. It is also useful as a biochemical index of esophageal varices in confirming or refuting the interpretations of radiologic and esophagoscopic methods.

10090 THE ESOPHAGEAL PROPULSIVE FORCE: ESOPHAGEAL RESPONSE TO ACUTE OBSTRUCTION. (E.) Winship, D. H. (Marquette U. Sch. Med., Milwaukee, Wis.) and F. F. Zboralske. J. Clin. Invest. 46(9):1391-1401, 1967.

In 11 (9 men, 2 women; 23-40 yr. old) healthy adult volunteers without evidence of esophageal disease, the response of the normal human esophagus to an obstructing intraluminal bolus was studied and compared to the response evoke by transient intraluminal distention. A ballo immobilized within the esophagus by external a tachment to a force transducer, was inflated w from 3-25 ml of air for 3-210 sec. Pressure phenomena occurring in the esophagus were simu taneously recorded from the body of the esopha above and below the balloon. Transient disten (5 sec. or less) with small vol. (5 ml or less often evoked a secondary peristaltic wave in t esophagus distal to the balloon, but infrequen resulted in the registration of any force exer upon the balloon to drive it downward. Conver distentions of longer duration and with greate vol. elicited an esophageal propulsive force e erted upon the balloon oriented to propel it aborally, and much less often evoked a propaga wave of secondary peristalsis. The propulsive force, obviously resulting from esophageal mus contraction, occurred promptly, and once initi was sustained until deflation of the balloon. It varied widely in magnitude, from 4-200 g, a was associated with no motor phenomena recorde from the body of the esophagus proximal or dis to the balloon which could account for its pre ence, onset, magnitude or duration. The force was inhibited by deglutition, but arrival of the primary peristaltic wave at the bolus resu in augmentation of the force. When the obstru ing balloon was freed from its attachment, the persistent, stationary force was converted to a propagated one that propelled the balloon before it. If the balloon was arrested before entering the stomach, the moving contraction w also arrested and the persistent propulsive fo acting upon the balloon was maintained. The velocity of the moving contraction wave was determined in great part by the resistance offer by the bolus. Unrestrained, the balloon was propelled aborally at 4-8 cm/sec. by the esoph propulsive force; when restrained by 50 g, the rate of passage was reduced to 0.2-0.8 cm/sec. The esophageal response to intraluminal distention is thus not limited to the uninterrupted wave of secondary peristalsis, but is versatil and is determined by the nature of the distending bolus. Transient distention by a mobile o collapsible bolus elicits the propagated secon peristaltic wave.

10091 THE LOWER ESOPHAGEAL INTRINSIC SPHINCTER AND THE MECHANISM OF REFLU EXPERIMENTAL OBSERVATIONS SUPPORTING A NEW CONCEPT. (E.) Anderson, H. N. (U. Washington Sch. Med., Seattle), K. J. May, Jr., G. P. Steinmetz, M. Ofstun, H. G. Harrison, R. M. Le and D. H. Dillard. Ann. Surg. 166(1):102-108, 1967.

Experimental observation on 82 dogs with a variety of surgical procedures confirmed the presence of a functional intrinsic lower esopha eal sphincter and established this as the prim anism for the prevention of esophageal reflux its attendant acid-peptic esophagitis. This r esophageal sphincter can function in the athoracic position, and it also functions in absence of the diaphragmatic pinchcock mechan- or the acute angle of entry into the stomach. he absence of a functional intrinsic sphincter, e other factors, alone or in combination, are pable of preventing reflux. In the dog, the al intrinsic lower esophageal sphincter is un- to function properly when interference with action is produced by distraction from ab- al traction or abnormal insertion of the noesophageal membrane into the esophagus or . This situation may occur in some humans may explain in some cases why reflux is an nstant finding with esophageal sliding hiatal ias.

2 A COMPARATIVE STUDY OF NATURALLY OCCURRING CANINE ACHALASIA. (E.) Hoffer, . (U. Pennsylvania Sch. Med., Philadelphia), aldes-Dapena and A. E. Baue. Arch. Surg. cago) 95(1):83-88, 1967.

ical and pathologic aspects of human and ne achalasia were compared, employing 25 dogs naturally occurring achalasia. Vomiting n 10-20 min. after eating or nursing during early stages of the disease, with the vomitus isting of mostly undigested food. The vomitus much more fluid in consistency during later ges, and in advanced achalasia consisted of a dorous, viscous fluid which was obtained when head was lowered. Physical examination re- ed poor nutrition, wt. loss and enlargement he metaphyses of long bones suggestive of kets. A dilated saccular esophagus was palp- above the thoracic inlet. Recurrent pneu- tis was observed in most dogs. Thoracic y revealed great dilatation of the esophagus, le fluoroscopy demonstrated a generalized phageal dilatation, absence of esophageal peri- sis, and passage of Ba into the stomach de- dent on the esophageal fluid level. A zone increased pressure, but within normal limits, observed in the distal esophagus. Two of the ogs treated by modified Heller procedure and y kibble diet showed normal esophageal di- ters at 5-mo. follow-up. Myenteric ganglion nts decreased with the duration of the disease. cellular reduction is considered secondary not causative of achalasia in the dogs studied. se findings suggest that further study of ine achalasia should prove helpful in the cidation of human achalasia.

3 THE VALUE OF PALLIATIVE PROSTHESES IN MALIGNANT LESIONS OF THE ESOPHAGUS.) Duvoisin, G. E., F. H. Ellis, Jr. and W. S. ne. Surg. Clin. N. Amer. 47(4):827-831, 1967.

ariety of prosthetic tubes were inserted in patients with malignant esophageal obstruction. phageal obstruction had caused almost all of them to experience difficulty in swallowing, which in many had progressed to allow only liquid intake. Symptoms had been present from 1 wk.-24 mo., av. approx. 5 mo., but in two-thirds they had been present less than 2 mo. Fistulous connections between the esophagus and the tracheobronchial tree were present in 7 patients. Wt. loss was observed in all but 2 cases (av. 24 pounds). Sites of the lesions were tabulated in 3 zones: the upper half of the thoracic esophagus (24%), the lower half (20%) and the esophagogastric junction (56%). Of the primary carcinomatous lesions examined, 46% were adenocarcinomas and 43% squamous-cell carcinomas. In 1 case, a cylindroma of the bronchus had extended directly into the esophagus. Celestin tubes were used in 59, Mackler tubes in 26, Berman tubes in 8 and the Tygon, and Mousseau-Barbin tubes in 1 each. There were 13 hospital deaths (14%); 4 were due to primary malignant disease, and intubation was implicated in the remaining 9. Fatal mediastinitis occurred in 5 cases after insertion of Mackler tubes. Of 93 patients in whom intubation was successfully accomplished, 42 developed 1 or more complications related directly to the tube or its insertion (including the 9 previously-mentioned fatal complications contributing to operative mortality). Wound infections were the most frequent problem, occurring in 20 cases (18 Celestin tubes, 2 Mackler). Serious complications such as obstruction, migration and gastrointestinal leaks were present in 29 patients, but the incidence was nearly twice as great with the Mackler tube as with the Celestin tube. Of those surviving insertion of Mackler tubes, 30% developed an obstruction, contrasted with only 11% in the Celestin-tube group. Massive gastrointestinal hemorrhage occurred in 7 patients with Celestin tubes and was fatal to all but one of them. The av. survival time of patients was 4.5 mo., with a range of 2 wk.-32 mo.; only 13 of 95 patients lived more than 6 mo. Adequate palliation was accomplished in 70% of the 73 patients evaluated, with the great majority swallowing well for 80% or more of their survival time. Only 56% (10) of those with Mackler tubes received adequate palliation, in contrast to 73% (35) of those with Celestin tubes. Generally patients with tracheoesophageal fistula did not benefit from palliative intubation. The Celestin tube provided the best palliation; those patients in whom a Celestin tube was employed had lesions which were more unfavorable both clinically and pathologically than those in the group who had Mackler tubes; yet the Celestin tubes were inserted with lower operative mortality, were associated with a lower incidence of significant complications and produced adequate palliation in a higher percentage of cases than the Mackler tubes.

10094 ANASTOMOSIS BETWEEN THORACIC DUCT AND ESOPHAGUS WITH MICROSURGICAL TECHNIQUE. (E.) Oh, C. Y. (Mt. Sinai Hosp., New York, N. Y.), M. C. H. Wang, C. A. Danese and J. H. Jacobson II. Surgery 62(2):340-345, 1967.

Anastomosis of the thoracic duct to the esophagus with microsurgical technics was performed in 55 dogs; they were divided into 3 groups: Group A, 36 normal animals; Group B, 14 with ascites produced by constriction of the supradiaphragmatic inferior vena cava; and Group C, 5 animals with ligation of the common bile duct. The latter 2 groups were used because they were the 2 pathological situations in which lymph flow was markedly increased, and where prolonged drainage of lymph appeared to have promise of clinical usefulness. Five types of thoracic duct-esophageal fistulas were constructed: edge-to-edge anastomosis, overlapping technic, subclavian anastomosis, intrathoracic jugular anastomosis and addition of stent (done in conjunction with the first 3 anastomoses); the actual anastomoses were not to the thoracic duct itself, but to venous structures. Jugular anastomosis to the intrathoracic esophagus was an attempt to utilize the massaging action of intermittent negative pressure developed during respiration to assist lymph flow and maintain patency of the anastomosis. No anastomosis patent beyond 1 wk. was observed in any of the animals, in spite of the variety of methods of fistula construction and production of increased lymph flow by interior thoracic vena cava constriction or common bile duct ligation. The principal cause of failure was the presence of excess granulation tissue at the site of anastomosis; in others, marked inflammatory changes due to anastomotic disruption were noted. In those with catheter stents, there were no anastomotic disruptions, but rather occlusions of the catheter lumen by blood clot and lymph clot. It is suggested that secretion of the gastrointestinal tract has an inflammatory action on vascular endothelium and leads to early occlusion by granulation tissue and eventual fibrosis of the vessel itself. The potential usefulness of this technic in treatment of ascites and biliary atresia makes enteric-thoracic duct fistula a goal worth achieving.

10095 AN EXPERIMENTAL STUDY OF THE GASTRO-ESOPHAGEAL REFLUX AND OF METHODS FOR ITS SURGICAL ELIMINATION. (Rus.) Kanshin, N. N. (Moscow Med. Inst.). Sovet. Med. 29(12):92-95, 1966.

Anatomic preparations of "stomach-cardia-esophagus" were made from cadavers by removal of the stomach with the gastric ligamentum and the lower portion of the esophagus, which was hermetically connected with a transparent sac (from polyethylene film); at the region of connection a ring was placed for easier attachment of the sac to the esophagus. One-third of the stomach was filled with a blue soln. and the region of the pylorus was ligated with a thread; the cephalic end was dropped at 30° angle. In Experiment 1, gastric fluid began to flow into the esophagus after increase of the angle of His to 60° or more. In Experiment 2, gastro-esophageal reflux was produced by pulling to the side of the esophagus, which increased the angle of His. In experiment 3, pulling of the esophagus in the cephalad direction caused dilatation of the gastro-esophageal angle and the
appearance of reflux. In Experiment 4, attac
of a small splint (for initiation of cardial
at the esophageal opening) caused leveling of
angle of His and created conditions for free
flow of gastric fluid into the esophagus. In
Experiment 5, formation of slight (artificial)
muscular tonus of "esophageal press" delayed
duction of reflux. In Experiment 6, placing
nodular sutures between the left esophageal w
and the gastric fundus markedly delayed the a
pearance of reflux. In Experiment 7, underne
suturing of the gastric fundus to the esophag
(at the larger surface) improved the results
esophagofundoraphy; it was most effective in
bination with initiation of muscular tonus of
"esophageal press". In Experiment 8, removal
the rubber strap and sutures resulted in discontinuing the function of the cardial valve
mechanism, even with a large esophagofundorap
In Experiment 9, longitudinal myocardiotomy b
the Heller technic, involving the cardia and
of the esophagus, produced reflux. All of th
experiments were repeated on 5 preparations.
Experiment 10 (studied on 10 preparations), f
plication according to Nissen always formed a
reliable flap valve in the cardial area; this
worked well even in the complete absence of t
of "esophageal press" and common rigidity of
esophageal wall. The cardia submerged into t
fold became impenetrable (moving toward the
esophagus) for water and air.

10096 VARIATIONS IN THE COLON ARTERIES STRUCTURE WITH REGARD TO COLONIC ESOPHAGOPLASTY. (Rus.) Shiriaev, I. I. (Odes Pirogov Med. Inst., USSR). Vestn. Khir. Greko 98(3):35-40, 1967.

A study made on 104 cadavers (76 males and 28
females who died at 12-86 yr. of age) revealed
basic forms of the structure of the colic arteries: 1) single-stem; 2) transitory, where
the basic stem is divided into 2 almost ident
thick branches; and 3) loose, wherein the col
artery is broken up into branches. In 51 of
preparations, the right colic artery as an independent stem was absent, the ileocolic, cen
and left colic arteries had a single-stem str
the left colic artery ascended vertically and
transplant could be formed from the transverse
colon with the splenic arc and from the desce
colon with the left third of the transverse c
In 32 of 104 preparations, the right colic ar
was absent; the ileocolic, central and left c
arteries had a loose structure, the left colic
artery passed up or ascended almost verticall
an extraorganic bond between the central and
colic arteries was absent; a transplant could
formed only in the region of the left half of
the colon. In 21 of 104 preparations, the ar
system of the colon was presented by 4 arteri
the ileocolic artery had a transitory structu
the right colic artery had a loose structure,
central and left colic arteries had a single-
structure; and the left colic artery passed u
and to the left into the region of the splenic
arc of the colon; a transplant could be formed

rom the transverse colon with the splenic arc, rom the descending colon with the left third of he transverse colon, and from two-thirds of the ransverse colon with the upper-half of the decending colon. An arterial system of the colon onsisting of 4 colic arteries of transitory form nabled formation of a transplant with a well-exressed marginal vessel: from the right half of he colon in an isoperistaltic position, from the ransverse colon with the splenic arc in the ntiperistaltic position, from the descending olon with the splenic arc in an antiperistaltic osition, and from the transverse colon with part f the descending colon in the isoperistaltic osition.

0097 PROGRESSIVE SYSTEMIC SCLEROSIS: II. ESOPHAGEAL INVOLVEMENT. CORRELATION ETWEEN BLIND BIOPSY OF THE ESOPHAGUS, ACID DRIP EST, AND RADIOLOGY. (E.) Bettarello, A. (Med. ch., Sao Paulo, Brazil), T. Brito and S. Zaterka. mer. J. Dig. Dis. 12(8):808-812, 1967.

total of 22 patients (18 female, 4 male; 21-56 r. old, with a mean of 34.3 yr.) with progressive ystemic sclerosis were examined by blind biopsy f the distal esophagus (with a modified Wood iopsy tube), X-ray examination of the esophagus nd the acid drip test (Bernstein and Baker test, s modified by Bettarello). The patients were ivided into 2 groups according to the presence r absence of heartburn. Of those with heartburn 15), the Bernstein test was positive in 14 93.3%); esophageal biopsy failed in 3 patients gastric mucosa instead of esophageal mucosa was btained), and 11 of the remaining 12 demonstrated sophagitis by biopsy; esophagitis could be adiologically demonstrated in only 3 patients f this group, and in 2 of them there was histologcal confirmation. Of 7 patients with no heartturn, the acid drip test was negative in all of hem; biopsy of the esophagus was successful in ll 7 patients, and in 2 of them esophagitis was bserved, but the inflammation was limited to he lamina propria. It is concluded that blind iopsy may be useful in the diagnosis of esophagtis in situations in which visualized biopsies annot be performed for technical reasons.

0098 CLINICAL, MANOMETRIC, AND PATHOLOGICAL STUDIES IN DIFFUSE OESOPHAGEAL SPASM. E.) Gillies, M. (Roy. Prince Alfred Hosp., ydney, Australia), R. Nicks and A. Skyring. rit. Med. J. 2(5551):527-530, 1967.

f 21 patients studied, 8 were under the age of 0, 7 between 40 and 60, and 6 over 60, with an qual sex distribution; all had histories of ntermittent episodes of dysphagia and chest ain, and the replacement of peristalsis by ynchronous contractions of the esophagus, often epetitive and of high pressure. Motility tudies were done using a direct writing polyraph connected to open-tipped, water-filled esophageal catheters by pressure transducers; simultaneous recordings were taken at 2 or 3 points 5 cm apart at 1-cm intervals throughout the length of the esophagus. Radiologic pictures of Ba swallows were done in all patients; the severity of the radiologic changes did not show a close correlation with the clinical, manometric or pathological findings. Analysis of motility patterns has better defined the abnormalities expected in patients with severe diffuse spasm; disturbances of motility occurred mainly in the mid- and lower-thirds, but in some patients, in the upper third. Synchronous activity was present after every swallow recorded in the lower esophagus and was present in the upper third in 8 of 10 swallows. Repetitive activity with 2-5 contractions after swallowing, and lasting up to 30 sec. each, was found in 20 patients; and in the upper-third in 10; contractions lasting longer than 6 sec. were present in the upper-third in 11 patients and in the lower 66% in all; duration ranged from 4-20 sec. In the lower 66% of the esophagus pressures after swallowing and during repetitive and spontaneous activity ranged from 20-120 mm Hg and were often greater than 60 60 mm Hg; mean resting pressure was from 5-25 mm Hg. Symptoms in 7 patients were severe enough for esophagomyotomy; all were relieved of pain and dysphagia and became asymptomatic; there were no complications; at operation it was noted that the esophageal muscle extending from the cardia to the level of the aortic arch was thickened; in some cases 2 cm thick. The other patients were managed conservatively for periods up to 4 yr.; later motility studies on these people were almost identical with the original studies.

10099 CLINICAL AND RADIOLOGIC ASPECTS OF CONGENITAL SHORT ESOPHAGUS. (It.) De Maria, A. (U. Rome) and G. Cocchieri. Arch. Chir. Torac. 21(1):25-50, 1967.

STOMACH

(Gastric ulcer is placed with peptic ulcer)

10141 PANCREATIC FUNCTION AND THE ABSORPTION OF FAT, IRON, VITAMIN B_{12} AND CALCIUM AFTER TOTAL GASTRECTOMY FOR GASTRIC CANCER. (E.)

Fischermann, K. (Blegdams Hosp., Copenhagen), S. Harly, H. Worning and A. Zacho. Gut 8(3): 260-266, 1967.

Twelve patients (7 male and 5 female, aged 45-73 yr.) who were treated by either Roux-Y or interposition type total gastrectomy were evaluated with respect to general condition, pancreatic function and absorption. No patient at follow-up (0.5-15 yr.) had postprandial complaints, dumping, or abnormal stool appearance, and all could ingest normal food portions. Serum protein distribution was within normal limits in all cases, however 2 patients did manifest moderate anemia and reduced serum Fe levels. Three patients with a follow-up of less than 1.5 yr. showed reduced Fe absorption. Ca retention after 7 days was below 12% (12-24% in 5 normal subjects) in 2 patients with a follow-up of less than 1 yr; however, both had normal serum levels of Ca. One patient with reduced serum Ca levels but with normal Ca absorption did manifest frank osteoporosis. The pH of the small intestine (except for the first portion) was significantly higher than that found in healthy persons with achlorhydria. The av. daily fecal excretion of fat in 3 patients with Roux-Y procedures was 18-55 g. It is concluded that when surgical anastomosis is well established, total gastrectomy for the treatment of gastric malignancy is a satisfactory procedure.

10142 ACID-BASE CHANGES AFTER GASTRIC SURGERY. (E.)

Parkin, G. (Gen. Infirm., Leeds, England), G. R. Giles and C. G. Clark. Brit. J. Surg. 54(7):629-632, 1967.

Alterations in acid-base balance in response to a test meal was examined by measuring the changes found in arterialized blood drawn from the back of the hand previously warmed. Test Meal 1 consisted of 500 ml of a milk mixture, 325/mOsmoles/kg, including 11.8 g protein, 34.4 g fat, 62.0 g carbohydrate, and a total of 592 calories; Test Meal 2 was also 500 ml of a milk mixture, 354/mOsmoles/kg, including 30.1 g protein, 16.2 g fat, 86.2 g carbohydrate and 603 total calories. These test meals were designed to minimize any effects of dumping by providing a feed with an osmolar conc. similar to that of small intestinal contents. Normal control subjects included 10 men (23-38 yr. old) and 6 women (23-51 yr. old); patients (26) who underwent gastric surgery were all men, 31-69 yr. old including 10 who had gastrectomy several mo. or yr. previously, 5 with a Polya gastrectomy, 4 with vagotomy and gastroenterostomy, and 7 with vagotomy and pyloroplasty. Results were variable after the first test meal. After the second test meal (in which the fat was decreased and the carbohydrate content increased), response in normal subjects was a mild metabolic alkalosis; change was max. in the first hr. and returned to the previous basal level by the third hr.; this corresponded to the period of acid secretion during the digestion of food. After the second test meal, an acidotic response was elicited in 4 of 5 patients with partial gastrectomy, 2 of 4 patients with vagotomy and gastroenterostomy, and 3 of 7 patients with vagotomy and pyloroplasty; a general correlation was found with acid secretion in that those patients with achlorhydria or low acid secretion showed greater metabolic acidosis when considered as a group. In patients studied several mo. or yr. after gastric resection a normal metabolic alkalotic response occurred in 3 where food passed into the duodenum, whereas metabolic acidosis was common in a group treated by Polya gastrectomy and, in 2 subjects with the most marked effect, symptoms of dumping syndrome occurred. In 2 subjects undergoing reconstructive surgery for postgastrectomy symptoms including dumping, the acidotic response was changed to an alkalotic response when food was diverted through the duodenum. These findings suggested that an abnormal metabolic acidotic response after gastric surgery may be due, at least in part, to the mechanics of gastric emptying. It is also suggested that the metabolic acidotic response to gastrectomy can persist for yr. after operatio and may bear a possible relationship to dumping,

10143 SERUM PROTEIN CHANGES AFTER GASTRECTOMY AS A MODEL OF ACUTE PHASE REACTION. (E.)

Werner, M. (Wilhelms U., Munster, Germany) and D. Odenthal. J. Lab. Clin. Med. 70(2): 302-310, 1967.

Changes in specific serum proteins were analyzed in 12 patients (10 men, 2 women; 36-72 yr. old) who underwent gastrectomy (7 had a Billroth I resection and 5 a Billroth II; 10 had gastric or duodenal ulcer, and 2 had gastric carcinoma) and who had an uneventful postoperative course. Serum samples were collected before and at 3-day intervals until the eighteenth postoperative day; individual proteins were estimated by radial immunodiffusion and enzymatic assay. The following temporary shifts in individual proteins accounted for changes in the electrophoretic pattern: Albumin conc. fell; α_1-globulins rose, due mostly to increased α_1-antitrypsin, and less to α_1-acid glycoprotein while α_1-lipoprotein simultaneously fell; α_2-globulins also rose, mostly due to increased haptoglobin, and much less to ceruloplasmin, while α_2-macroglobulin remained unchanged; β-globulins decreased, due to falling transferrin and β-lipoprotein. These changes corresponded to those observed in acute inflammatory disease. Gastrectomy offers the opportunity to study the acute phase reaction in a model under uniform conditions since the degree of injury is similar and the onset of the organism's reaction can be accurately timed.

HYPERGLYCEMIA AFTER GASTRECTOMY AS A
PREDIABETIC STATE. CLINICAL STUDY OF
OSTGASTRECTOMY PATIENTS. (E.) Tobe, T.
n Baptist Hosp., Kyoto), M. Kouchi, H.
ura and C. H. Huang. Arch. Surg. (Chicago)
:836-840, 1967.

most normal and differentiable from the
in diabetic patients. Histological find-
n the pancreas of older patients whose
rative glucose tolerance test curves were
al frequently revealed degranulation or
ization in the β-cells of the islets of
hans. In this series, 2 patients, whose
e tolerance test curves showed oxyhyper-
ia preoperatively, developed a diabetic
n 3 mo. and 10 mo. afterward, resp. Five
ts who had a family history of diabetes
abnormal glucose tolerance test curves
eratively. It is concluded that patients
family history of diabetes and those over
of age should be followed as prediabetics.

THE IMPORTANCE OF PRESERVING OPERATIVE
PROCEDURES ON THE STOMACH. (Rus.)
nikov, V. A. (Sverdlovsk Med. Inst., USSR)
K. Kurchavov. Vestn. Khir. Grekov 98(4):
1967.

numan and 20 canine organ complexes a large
ility was found in the branching of both
of the vagus nerve and its interrelation
he elements of the sympathetic nervous
. Twenty of 30 dogs had surgery by Bill-
with Hoffmeister-Finsterer modification
had Billroth 1 with preservation of both
and organic branches of the vagus nerves.
15 patients had establishment of gastro-
l anastomosis; a resection line was marked,
to this line up to the anterior part of
odenum all the vessels entering the anterior and posterior gastric wall at a distance of 1.0-1.5 cm from the small curvature were sutured by silk; peripheral ends at a distance of 1.5 cm from first line sutures were also ligated; then the gastric serous-muscular path with adjoining descending branches of the left gastric artery, basic trunks of the anterior and posterior cord of vagus nerve and their multiple organic branches passing in the small omentum, was isolated. After duodenal resection, the stomach was resected and gastroduodenal anastomosis established; the end of the path was sutured and the latter fixed lengthwise to the small gastric curvature. This method completely preserved both cords of the vagus nerve with multiple interorganic branches and even perivascular nerve plexus, and with a gastroduodenal anastomosis nutritional masses, passing through the duodenum, caused suitable reflexes with its mucous membrane, necessary for the liver and pancreas. Postsurgical course in dogs with this gastric resection was smoother than in dogs with typical gastric resection, which refused food, vomited, lost wt. and had fluid stools. One clinical case history of successful use of this method is presented in detail. Such method could be used at any localization of ulcerative process and at complications of peptic ulcers (hemorrhage, perforation, stenosis); however, its use should be specially studied in ulcers of the lesser curvature due to the possibility of their malignant transformation, as well as for duodenal ulcers located lower.

10146 CANCER OF THE STOMACH. (E.)
Veidenheimer, M. C. and C. J. H. Logan.
Surg. Clin. N. Amer. 47(3):621-626, 1967.

During the 10-yr. period from June, 1948-May, 1958, 687 patients (447 men, 240 women; av. age 59.7 yr.) with previously untreated malignant disease of the stomach were treated at the Lahey Clinic Foundation with a followup rate of 99.3%. Initial complaints of this group varied greatly, but wt. loss, anorexia and indigestion was most common; some had vomiting and hematemesis or melena; 66% had a wt. loss of more than 10 pounds, and 34% lost more than 20 pounds. Forty-two % of the patients had symptoms for longer than 6 mo., and 82% had symptoms for less than 1 yr. Physical examination revealed normal findings in 492 (71.6%); a palpable mass or clinical evidence of metastatic disease was present in 28.4%. Studies of gastric acidity performed on 308 patients revealed that 50% had a level of acidity that was either normal or above normal. X-ray study resulted in a correct diagnosis in 87.1% of the patients examined; an additional 6.2% of the patients examined were believed by radiologists to have a lesion highly suspicious of cancer; incorrect radiologic diagnosis was made on only 6.7% of the entire series. Resection of the stomach was possible in 407 patients (59.4%); of the remaining 278, 181 had biopsy alone, 58 had laparotomy without biopsy, 26 had a simple gastroenterostomy, 1 had a gastrostomy, and in 12, other various nonresective procedures were done. Gastric resection was palliative in 148, and thus there were 259 patients on whom resective surgery was performed with hope of cure. There were 13 basic pathologic types of tumor found, the most common being carcinoma simplex, found in 268 and adenocarcinoma, found in 247. Site of the gastric carcinoma was in the antrum in 204 (30.1%), lesser curvature in 164 (23.9%), greater curvature in 56 (8.2%), cardia in 173 (25.2%), entire stomach in 62 (9.0%) and unspecified in 23 (3.3%). A total of 255 patients (51.7%) presented positive evidence of lymph node metastases; 125 (18.2%) displayed no evidence of lymph node involvement. The remaining 207 patients (30.1%) did not have definite evidence of either involvement or absence of involvement of lymph nodes at time of surgery. Operative mortality for 100 patients undergoing total gastrectomy was 9%, and that for 307 undergoing subtotal gastrectomy was 3.9%; for the entire group of 407 patients, it was 6.9%. For the 407 patients undergoing resections, the 5-yr. survival rate was 23.1% and the 10-yr. survival rate was 13.3%. For those undergoing resection with hope of cure the 5-yr. survival rate was 36.2%, and the 10-yr. survival rate was 18.5%. When survival was related to lymph node involvement, the 5-yr. survival rate was 7.6% and the 10-yr. survival rate, 0.8%, for those with lymph node involvement, and the 5-yr. and 10-yr. survival rates were 47.3 and 18.4%, resp., for those without lymph node involvement. Absolute survival of the 687 patients with cancer of the stomach revealed that 5-yr. survival (684 cases) was 13.7% (94) and the 10-yr. survival (445 cases) was 6.5% (29).

10147 SURGICAL TREATMENT OF CANCER IN THE PROXIMAL PORTION OF THE STOMACH.

(Rus.) Peterson, B. E. (Cent. Inst. Postgrad. Med., Moscow) and K. Zh. Musul'manbekov. *Vestn. Akad. Med. Nauk SSSR* 22(5):48-55, 1967.

Postsurgical mortality of cardial cancer according to the latest literature (1959-65) av. 15-20% (range 3.2-39.9%) while the cases studied here of 140 patients in 1966 av. 22.9%. In the last 6-yr. period, of 291 patients (226 males, 65 females) treated for cancer of the proximal part of the stomach, 229 had surgery (e.g. gastrectomy or cardial resection in 140 (age 20 - over 70 yr.), pallative surgery in 38 and exploratory thoracotomy and laparotomy in 51, part of whom had subsequent chemotherapy, while the remaining patients were treated by therapeutic compounds. Lethal outcome following surgery occurred in 32 of 140, 4 of 38 and 1 of 51, resp. Seven of 140 were operated in Stage 2 of the disease and the remaining in Stages 3-4; in 103 surgery was performed in those older than 50 yr. Tumor transition to the esophagus was found in all patients with cardio-esophageal cancer, in 35 with subcardial cancer and in 2 of 8 with fundal cancer. Of 122 with subcardial cancer surgery could be performed in 54 (resection of the proximal part
in 16 and gastrectomy in 38); of 99 with card
esophageal cancer 78 had surgery (e.g. 56 and
resp.), while 8 with fundal cancer had gastre
tomy. Resection of the proximal part of the
stomach by thoracic access had 45 (6 dead) by
abdominal access 19 (3), and by combined acce
6 (2); the resp. values for gastrectomy are 2
(6), 35 (9), and 11 (6). Surgery was combine
in 63 cases. Death was due to faulty sutures
anastomoses in 10 (death occurred by day 2-30
after surgery), pulmonary-pleural complicatio
in 6, purulent complications in 4, internal a
adrenal hemorrhages, 3, cardiovascular compli
tions, jejunal loop gangrene, insufficiency o
gastric stump and organic wall at the site of
fixation to the diaphragm, 2 each, shock,
thromboembolism of the pulmonary arteries, ac
pancreatitis, 1 each. Bypass anastomosis in
patients resulted in 1 death from faulty sutu
During 1964-66, 7 of 55 operated patients die
(12.7%); this decrease was mostly due to more
careful preparation of the patients for surge
standardization of the surgical technics and
more rational post-surgical supervision of
patients. Esophageal resection of 10 cm or
is recommended.

10148 MOTOR FUNCTION OF THE STOMACH FOLL
RESECTION OF ITS CARDIAL PORTION I
CONNECTION WITH CANCER.

(Rus.) Zheleznyi,
(Nagatinsk Line Hosp. for Moscow-Oksino-Volga
Water Transport Workers, USSR) and S. S. Mor
Sovet. Med. 29(12):26-30, 1966.

The motor function of the stomach (rhythm of
biopotential fluctuation, max. and minimum
potential, potential difference, av. biopote
was studied in 30 patients 10 days-16 yr. af
cardiectomy for cancer of the proximal porti
of the stomach and in 10 persons without dis
of the gastrointestinal tract; radiology and
electro-gastrograms were employed in this st
Up to 30 days after resection, the motor act
of the gastric stump was markedly disturbed,
showing a decreased value for all components
especially of rhythm (2.1 fluctuations/min.,
compared to the normal of 3 fluctuations/min
A further decrease of all electro-gastrogram
indices occurred in the period from 1-6 mo.
after surgery, and it was conditioned by a
depression of motor activity and abatement o
postsurgical inflammatory symptoms in the st
wall; X-ray revealed atony of the stump,
peristalsis of the wall was inert, and evacu
from the stump was passive. Some improvemen
motor activity of the gastric stump was evid
6-18 mo. after surgery and was manifested by
increase of electrogastrogram indices; gastr
evacuation was more delayed. Electrogastrog
indices showed further increase during 1.5-5
yr. after surgery, and approached normal in
of the cases; however, fluctuation rhythm wa
still delayed. X-ray showed peristalsis of
gastric wall, and evacuation was somewhat
delayed. At observation more than 5 yr. aft
surgery, a further restoration of gastric mo

ity was noted, and in some patients, the
ces were normal. Therefore a marked decrease
tor function of the stump was evident at an
stage after resection; improvement began
o. after operation, but normalization
red much later. Vagus regeneration was
ed in 16 persons who died 2 mo.-16 yr. after
ry; regeneration had already occurred 6-7
fter surgery, while a pronounced regeneration
oted much later (10 yr.).

COPPER METABOLISM IN DOGS AFTER
GASTRECTOMY AND RESECTIONS OF VARIOUS
NTS OF THE STOMACH. (Rus.) Kovtuniak,
(Ivano-Frankovsky Med. Inst., USSR). Biull.
Biol. Med. 63(6):37-40, 1967.

study was made on 7 dogs after gastrectomy
establishment of esophagojejunoanastomosis
p 1), on 7 animals after resection of the
oduodenal portion of the stomach according
e Billroth II technic (Group 2) and on 7
after segmental resection of the body of the
ch (Group 3), while 6 dogs served as con-
after laparotomy. Progressive wt. loss
a lethal outcome occurred toward the end of
-9 mo. in Group 1 and after 10-12 mo. in
2, but dogs in Group 3 showed less wt. loss
urvived more than 2 yr. In controls, whole
and blood ultrafiltrate content of Cu before
fter surgery remained practically unchanged,
95 and 41 µg%, resp., while the Cu content
gans and tissues was the same as in healthy
ls. In Group 1, Cu content in whole blood
lood ultrafiltrate before surgery was 102
0 µg%, resp., while after surgery, whole
content decreased to 65 µg%, and that of
lood ultrafiltrate in the first 2 mo.
ased to 136 µg% with a subsequent decrease
ing, in the terminal period, twice the lower
which prevailed before surgery. In contrast
ntrols, a marked decrease in the Cu level
ound in the spongiosa substance of the
opoietic portion of the osseous epiphyses,
, liver, pancreas, kidneys and muscles. In
2, Cu content of whole blood by 10-30
after surgery remained practically unchanged,
hat of the blood ultrafiltrate was decreased;
the second mo. onward, Cu content showed a
lel increase in whole blood and blood ultra-
ate, while the latter decreased, in the
al stages, approaching initial levels; the
tent in previously-mentioned organs and
es was markedly decreased. In Group 3, Cu
in whole blood and blood ultrafiltrate
ed unchanged 8-9 mo. after surgery, while
9-10 mo. and for 2 yr. its content in both
lly increased. Cu conc. in organs and
es was the same as in controls.

THE ROLE OF THE NERVOUS SYSTEM IN THE
PATHOGENESIS OF THE DUMPING SYNDROME.
Silver, D. (Duke U. Med. Ctr., Durham,
, D. Rignault and F. H. McGregor, Jr.
y 62(1):148-154, 1967.

Healthy mongrel dogs (6), not previously operated upon, received an intrajejunal dumping challenge of 150 ml of 50% glucose; 5-20 min. after challenge, portal blood was obtained and 220 ml of each of the resulting plasmas was admin. i.v. into a recipient animal; 2 of the recipients dumped, 2 exhibited only 3-4 of the dumping changes and 2 had no response. It is concluded that dumping signs could be produced by transfusion of plasma alone. The responses of 12 dogs with innervated blind jejunocutaneous fistulas to a dumping challenge were compared to responses of 12 dogs with denervated blind jejunocutaneous fistulas; each of the innervated dogs was challenged 6 times and had a dumping syndrome each time; each of the denervated animals was challenged 3 times, and none of these exhibited any signs of dumping. Twenty-three dogs with previously prepared innervated blind jejunal fistulas or Roux-en-Y jejunal fistulas were subjected to a variety of nerve interrupting procedures; all exhibited dumping before denervation. Vagotomy (8 dogs), bilateral splanchnicectomy (4 dogs), bilateral splanchnicectomy and extensive bilateral abdominal sympathectomy (2 dogs), and vagotomy and splanchnicectomy (4 dogs) had no effect on the response to a dumping challenge. Vagotomy, bilateral splanchnicectomy and extensive abdominal sympathectomy delayed onset of the standard dumping response by 20 min. Three dogs underwent chordotomy at the C_7 level and vagotomy; none had more than 2 dumping signs and these were delayed in appearance to 30-75 min. A conditioned dumping syndrome, observed in 2 animals with innervated blind jejunocutaneous fistulas, suggested the cerebral cortex plays a role in the dumping syndrome. Alterations in serotonin conc. after a dumping challenge revealed that dumpers (innervated) and nondumpers (denervated) had similar changes in serotonin conc., indicating that serotinin was not responsible for the dumping signs. The results of these experiments do not confirm the presence of a transferrable humoral agent in the dumping syndrome and suggest that, while the importance of humoral agents in their roles as neurotransmitters is not discounted, the nervous system has the major role in the dumping syndrome.

10151 JEJUNOSTOMY IN THE HIGH RISK GASTRECTOMY PATIENT. (E.) Rogers, J. C. T. (Carle Mem. Hosp., Urbana, Ill.). Surg. Gynec. Obstet. 125(2):333-336, 1967.

High jejunal tube enterostomy for gastric decompression was performed in 36 partially gastrectomized patients (24 males, 12 females; 30-81 yr. old, with 20 being between 50-69 yr. old), most of whom were in the increased risk category (risk factors generally referable to the respiratory tract). Seventeen of the 36 patients had chronic duodenal ulcers with such diverse complications as obstruction, bleeding intractability and chronic perforation; 1 had an acute perforation. Ten patients had gastric ulcerations including those with chronic perforation, bleeding and chronic ulceration. Of 3 with bleeding gastric ulcers, 2 were due to steroid therapy in patients with arthritis. Three patients had hypertrophic gastritis, 3 carcinoma, 1 fibroxanthoma, and 1 a gastrojejunal ulcer. There were no deaths, and other than 2 superficial staphylococcal skin infections, there were no immediate or late untoward sequelae. This type of jejunostomy for decompression circumvents the nasopharyngeal, esophageal and epiglottic trauma and the possible complications attendant to the inlying nasogastric tube. The psychic trauma factor is absent, so that sedation is minimized in many patients. Ambulation is easy, and throat irritation and dysphagia do not occur. The jejunostomy tube may remain in place as long as necessary without fear of complications; therefore repeated intubations are unnecessary. The tube, as placed in the efferent jejunal limb of the gastroenterostomy, may play a part in the prevention of kinking and dysfunction. The jejunostomy tube being in the dependent portion of the stomach makes simple gravity drainage effective. The operative procedure is simple.

10152 PYLOROJEJUNOSTOMY. (E.) Pecora, D. V. (VA Hosp., Altoona, Pa.). Amer. Surg. 33(9):737-738, 1967.

The technic of pylorojejunostomy was used in 26 patients with benign peptic ulcer; with this method, a loop of jejunum is anastomosed to the pylorus in an isoperistaltic manner. There was no morbidity or mortality due to the technic. All patients were carefully followed for up to 18 mo.; gastrointestinal radiology indicated that function was at least as good as that after successful pyloroplasty. Repeated determinations of 12-hr. excretion of free acid showed that these patients were consistently achlorhydric. All patients maintained good nutrition and were able to take regular diets; there were no recurrences of ulceration or bleeding, and none had symptoms suggestive of dumping. This preliminary experience with pylorojejunostomy indicates that it is safe and offers the advantages of pyloroplasty in cases in which scarring tends to interfere with safe construction. This procedure also allows the use of the incised jejunum as a pyloric patch. The disadvantages of gastroenterostomy are avoided, since only the most distal portion of the stomach is exposed to alkaline secretions. Gastrointestinal radiography also has shown that the gastric contents appear to follow a relatively normal course through the pylorus, duodenum and jejunum.

10153 THE REVISED COMBINED OPERATION WITH SELECTIVE GASTRIC VAGOTOMY. (E.) Harkins, H. N. (U. Washington Sch. Med., Seattle), C. A. Griffith and L. M. Nyhus. Amer. Surg. 33(7):510-513, 1967.

The results obtained from 212 patients who w
vagotomized by a selective technic which cau
the stomach to be vagotomized while the extr
gastric branches were spared, indicate that
technic is preferable to the standard tranca
technic. A relative looseness or frequency
postoperative intestinal movements (without
dumping symptoms) occurred in 38% of 60 pati
treated by the combined operation of antrect
plus trancal vagotomy plus gastroduodenal
anastomosis as opposed to only 2% of 52 pati
treated by the same operations except that t
vagotomy was a selective gastric one. In
addition, serious intractable postoperative
diarrhea occurred (without concomitant dumpi
in 4% of the truncal vagotomy cases as oppos
to 0% of the selective operations. There wa
only 1 recurrent ulcer. The incidence of po
tive Hollander tests in the 76 cases subject
to the test was 8%, indicating that the stom
is generally completely vagotomized by this
technic. There were 3 deaths: 2 of these (
and 73 yr. old) had acute massive hemorrhage
an indication for emergency operations.
Furthermore, the third, (a 35-yr.-old man),
a history of 2 incidents of massive hemorrha
The procedure concomitant with the selective
vagotomy was antrectomy plus Billroth I in 1
cases, pyloroplasty in 95 cases and none in
cases.

10154 TRANSILLUMINATED DISTENTION GASTRO
TOMY: A PRELIMINARY REPORT OF A
SIMPLIFIED METHOD EMPLOYING AN ILLUMINATED G
TRIC CATHETER. (E.) Edlich, R. F. (U.
Minnesota Med. Sch., Minneapolis), M. V. Pre
M. S. Tsung, W. P. Ritchie, Jr. and O. H.
Wangensteen. Surgery 62(3):448-451, 1967.

An illuminated trocar gastrostomy technic is
described; it is easily performed and quickl
carried out, and was performed over a 2-yr.
period upon 18 dogs without morbidity or dea
The operative time for the procedure was
uniformly less than 15 min., and every anima
accepted fluid through the gastrostomy tube
within a few days with no evidence of extra-
vasation of fluid into the peritoneal cavity
After catheter removal, the gastrostomy site
was obliterated within 14 days. The simplic
and attractiveness of this technic reside i
circumstance that ready access to the anteri
wall of the stomach can be gained through a
small, subcostal incision; inflation of the
stomach with air brings the anterior stomach
wall into direct contact with the parietal p
neum. This method appears to be adaptable t

10155 EXPERIMENTAL TROCAR GASTROSTOMY.
Jascalevich, M. E. (New Jersey Col
Med., Jersey City). Surgery 62(3):452-453,

A new technic for gastric aspiration or alim
tion which consists of a nonlaparotomic, rap

rcutaneous, trocar gastrostomy is described,
sed upon experiments on 25 dogs. A Levin tube
passed p.o. and the stomach forcefully ex-
nded by several strokes of the inflator; in its
lated form, the stomach is brought beneath the
vel of the costal margin and, displacing the
lon downwards, is placed near anterior abdominal
rietes, without any other visceral inter-
sition; tympanism to percussion confirms the
derlying presence of the dilated stomach.
er this area, high and flush to the costal
rgin, a point incision is placed through the
n only, and the trocar (modified Hurwitz, in
s series) is carried into the stomach by a
gle rapid stroke. A catheter is passed through
sheath of the trocar, the balloon of the
vin tube is inflated and the sheath withdrawn.
catheter is pulled out tight in order to
ng the anterior gastric wall against the
erior parietal peritoneum. Percutaneous
nsgastric tube suction or feeding can be
rted immediately. This technic was con-
tently successful in establishing a gastro-
ma in all 25 dogs operated upon. On explora-
y laparotomy, which was done systematically
er each catheter insertion, no injuries to
on, liver or other viscera were noted.
ragastric or intra-abdominal bleeding was
imal; this was probably due to the fact that
balloon of the tautly-pulled catheter
rted a hemostatic compression over the edges
the gastrostoma. Withdrawal of the tube
er deflation of its balloon was followed
sistently by the spontaneous closure of the
trocutaneous fistula after 24-48 hr. This
hnic was valuable for feeding large animals
the laboratory, and may have possible clinical
lications for the treatment of selected cases
in comatose patients after cerebrovascular
idents or severe head trauma and shock) in
ch an expeditious, nonoperative gastrostomy
desirable for feeding or suction purposes.

6 ISOTOPE UPTAKE AND SCANNING OF STOMACH
IN MAN WITH ^{99m}Tc-PERTECHNETATE. (E.)
den, R. McG. (Western Infirm., Glasgow,
tland), W. D. Alexander and I. Kennedy.
cet 1(7503):1305-1307, 1967.

2 subjects (28-69 yr.) 10 were volunteers
no evidence of alimentary disease; a 65-yr.-
woman had an incarcerated hiatus hernia with
greater part of the stomach lying in the
rax; a male had a total gastrectomy. All
fasted 10-12 hr. before scanning. A tracer
of 800 μc ^{99m}Tc-pertechnetate was inj. i.v.
the resulting radiation dose to stomach
thyroid being less than 0.2 rem. The
men was scanned in the anteroposterior
tion at intervals up to 1 hr. after the
er dose. Scans taking approx. 20 min. were
ined with a speed of 80 cm/min. and a line
ing of 0.5 cm. In all, the stomach was
rly displayed within 15 min. of isotope inj.
he patient with incarcerated hiatus hernia,
activity was localized mainly above the xiphisternum. Av. uptake (% dose) in controls at 6, 20 and 60 min., resp., were: 1.2 (range 0-2.5); 3.0 (0.4-5.5); 6.8 (2.4-11.4). One patient was scanned at intervals up to 130 min. The scans were repeated on a second occasion, when 500 mg of crushed potassium pertechnetate was given at 80 min. By 1 hr., the uptake was 4.7% dose; by 130 min., 6.7%. On the second occasion the 80-min. value was 3.6%; 45 min. after admin. of potassium pertechnetate (125 min.) gastric uptake had fallen to zero. Advantages of this scanning technic are stressed.

10157 GASTRIC ASPIRATION IN FIBER OPTIC ENDOSCOPY. (E.) Waye, J. D. (City Hosp. Ctr., Elmhurst, N. Y.), E. Pitman and K. Krueger. Amer. J. Dig. Dis. 12(7):705-707, 1967.

Nonemergency fiber optic gastroscopies (100) were performed with and without preceding gastric aspiration. All patients underwent gastroscopy with the Hirschowitz fiber optic gastroduodenoscope (Fiberscope), and many also underwent esophagoscopy with the LoPresti foroblique fiber optic esophagoscope. All patients were fasted for 12 hr. before examination. Of the first 50 patients studied, alternate patients had gastric aspiration with the Ewald tube after pharyngeal anesthetization; the av. vol of aspirate was 20 ml, with a range of 0-45 ml. The remaining 25 patients had gastroscopy without prior gastric aspiration. No difference was evident in ease of visualization between the groups with and without aspiration; it was found that a clear image could always be obtained by judicious instillation of air coupled with positional changes. None of the 25 patients who did not undergo aspiration required removal of the gastroscope and subsequent aspiration of gastric contents. Based on this initial experience, the next 50 consecutive patients underwent gastroscopy without preceding gastric aspiration; of these 50 patients, only 1 had unsatisfactory gastroscopy due to the presence of fluid and required subsequent gastric aspiration. Gastric juice in the amount of 120 ml was obtained, after which successful gastroscopy was performed; this patient was subsequently found to have pyloric obstruction secondary to active duodenal ulcer disease. It is suggested that pre-endoscopic gastric emptying is of little value in nonemergency procedures.

10158 EXPERIMENTAL STUDY OF THE PATHOGENESIS OF CONGENITAL HYPERTROPHIC PYLORIC STENOSIS IN PUPPIES. (E.) Mishalany, H. (American U. Hosp., Beirut). J. Pediat. Surg. 2(3):212-214, 1967.

In the present study a partial obstruction of the pyloric outlet (at the level of the pyloric sphincter) was created to determine whether or not a pyloric tumor is produced by work hypertrophy of the pyloric musculature proximal to

LIBRARY U. OF I. URBANA-CHAMPAIGN

the obstruction. Partial occlusions were created in 21 mongrel dogs between 1-9 wk. as these animals are known to develop congenital hypertrophic pyloric stenosis in much the same manner as humans. All dogs were fed milk postoperatively and were autopsied at varying times within the 7 postoperative wk. These animals were seen to have proximal dilatation and muscle hypertrophy of the pylorus, body and fundus of the stomach but no localized muscular hypertrophy of the pyloric canal in the form of tumor growth was seen, as might be expected from the application of the Lehman theory. The objection could be raised that the constricting suture was not present from the first day of life and so might not duplicate all the physiologic effects of pylorospasm. It was assumed, however, that a 1-day-old muscle would not behave so differently from a 1-mo.-old muscle under the same conditions of stimulus. The results of this study do not support Lehman's theory of the pathogenesis of congenital hypertrophic pyloric stenosis.

10159 RELATIONSHIP BETWEEN ASPIRIN TAKING AND GASTRODUODENAL HAEMORRHAGE. (E.) Parry, D. J. (West Middlesex Hosp., Isleworth, England) and P. H. N. Wood. Gut 8(3):301-307, 1967.

Of 542 patients without overt hemorrhage, 32% had a history of aspirin ingestion during the wk. prior to hospital admission, while 69% of the patients admitted with evident hemorrhage did have a positive history of aspirin intake. The times of aspirin ingestion and the frequency were similar in both hemorrhagic and nonhemorrhagic patients. Of the 95 patients with major hemorrhage, 15 had conditions encountered only infrequently (carcinoma of the stomach, hiatus hernia), 6 had negative histories and 9 had other conditions. Negative history of aspirin intake was noted in 22 of the 45 with proven peptic ulcer. In studies of possible aspirin-induced occult hemorrhage, no significant difference in susceptibility was observed in comparing patients with either active peptic ulcer or with recent hemorrhage with patients demonstrating normal gastrointestinal tracts. Although aspirin ingestion can be linked with the development of overt hemorrhage, no definite relationship can be offered at this time. It is concluded that patients without identifiable gastrointestinal pathology have the greatest risk from aspirin ingestion.

10160 CHRONIC GASTRITIS IN CHILDHOOD. (E.) Sedláčková, M. (Charles U., Prague) and B. Bednář. Gastroenterologia (Basel) 107(4):251-258, 1967.

Biopsy of the gastric mucosa was obtained from 131 children who were 2-18 yr. old. These 131 children were divided into 3 groups: Group 1, 54 without any gastrointestinal complaints; Group 2, 40 with abdominal pains, in whom the usual clinical examinations did not detect any organic cause of their disorders; and Group 3, 37 whose abdominal pains were explained clinically (duodenal ulcer, pathological, parasitolo ical, and bacteriological findings, cholecystopathy, abdominal epilepsy, and others). Chroni gastritis was found in 36 (28%) of the entire group. In Group 1, 13 (24%) of 54, in Group 2, 14 (35%) of 40 and in Group 3, 9 (24.4%) of 37 children had chronic gastritis, resp. The highest percentage of chronic gastritis was found in children 15 yr. of age (50%); in these children, advanced histological changes of the gastric mucosa were found. It is suggested th chronic gastritis originates long before adulthood, e.g., in childhood, and may have an asymptomatic course.

10161 ARGENTAFFIN CELLS IN EXPERIMENTAL GASTRITIS. (Sp.) Rodriguez Olleros A. (U. Puerto Rico, San Juan) and R. Barroso Moguel. Bol. Asoc. Med. P. Rico 59(6):243-246 1967.

The number and distribution of argentaffin cel in the gastric mucosa were studied (modified Rios-Ortega method) in 3 groups of animals wit experimentally-induced gastritis. Atrophic gastritis was produced in rabbits of Group 1 b desensitization with antigens from human gastr juice (12 mg in saline) admin. twice a wk. for 12 wk.; the number of argentaffin cells in the animals was markedly diminished as compared tc the number observed in rabbits with normal gastric mucosa. Papillomatous gastritis was induced in rabbits of Group 2 by inj. of 1-1. ml of a 0.5% alcohol-ether soln. of croton oi twice a wk. for 6-9 wk.; the number of argenta cells in these animals was markedly increased compared to controls during the early necroti stage, while the cells were displaced from th twelfth inj. or during the papilloma-formatio stage. Erosive gastritis was induced in dogs Group 3 by the weekly admin. of 2 g of cincho (Atophan) (duration of experiment not specifi no argentaffin cells were present in these animals during the necrotic stage accompanied by edema and metaplasia of the mucosa. The possible role of local production of serotoni by the argentaffine cells of the gastric muco in the development and symptomatology of gast tis is discussed.

10162 WEIGHT OF THE HUMAN STOMACH. (Rus. Klein, E. G. (Kiev Province Bureau Forensic Med., USSR) and A. Ia. Krishtul. Ar Pat. 29(4):53-58, 1967.

Human cadavers (age up to 1 yr. in 69 cases, 2-19 yr. in 101, 20-100 yr. in 232, embryos 5 mo. in 14) without gastric pathology (died suddenly of trauma with rapid death) were studied. Stomach wt. in male embryos was 0.6 at 5 mo., 0.9 at 6 mo., 2.5 at 7-8 mo., and 3 at 10 mo. In boy and girl newborns it was 4. and 4.4, resp.; at age 1-12 mo. it varied bet

-32.9 and 10.0-22.0, resp.; at age 2-10 yr.,
een 38.3-83.0 and 38.3-75.0, resp., at age
9 yr., between 71.2-180.0 and 82.5-160.0,
; in male and female adults, age 20-49 yr. it
ed between 153.3-160.0 and 142.5-149.5,
.; at age 50-89 yr. between 125.0-160.2 and
0-146.7, resp.; and in 7 females age 90-101,
as 105.7. Stomach wt. increase was irregular
was always lower in females than in males.
ease in organ mass was pronounced in the
t yr. after birth. Toward 20 yr. of age
ach wt. in males reached 160 g, e.g., it
eased 37.2 times since birth. Senile stomach
phy appeared in males at age 80-89 yr., and
ach wt. reached an av. of 125 g; in females
le stomach atrophy appeared 10 yr. earlier
the wt. was 124.6 g. In senile atrophy of
ach and signs of senile cachexia, stomach wt.
ingle cases decreased to 70 g. Direct
tive correlation between stomach wt. and body
was found in most of the age groups (correla-
coefficient varied between 0.6-1).

3 GASTRIC SHIGELLOSIS IN RHESUS MONKEYS.
(E.). Kent, T. H. (Walter Reed Army
. Res., Washington, D. C.), S. B. Formal,
. LaBrec, H. Sprinz and R. M. Maenza. Amer.
ath. 51(2):259-267, 1967.

us monkeys (20) were fed virulent Shigella
neri organisms and the stomachs were examined
,3,4,7 and 8 days after challenge. Grossly,
st 50%, and microscopically more than 66%
he animals had gastric lesions as early as 2
after challenge. The lesions were most
re at 3-4 days, but they persisted to 8 days.
0 animals, 16 had gastric lesions while 19
colonic lesions of shigellosis. In Giemsa-
ned sections large bacilli were demonstrated
he lesions. The fluorescent antibody technic
ifically identified these bacteria as
ella. S. flexneri was cultured from the
achs of 13 of 16 animals with gastric lesions.
e appeared to be no relationship between pH
astric contents and the occurrence of gastric
ons or the recovery of Shigella organisms
gastric contents.

BIOELECTRICAL ACTIVITY IN GASTRIC
BRANCHES OF THE VAGUS IN BROWN-PEARCE
OMA IN THE GASTRIC WALLS OF RABBITS. (Rus.)
tin, B. Z. (Khabarovsk Med. Inst., USSR).
l. Eksp. Biol. Med. 63(5):85-86, 1967.

n-Pearce sarcoma was induced by 0.2-0.4 ml
umor suspension admin. 12-14 days earlier
the anterior wall of the antral part of
it stomachs. In controls, electrical
vity (afferent impulse activity) in the
cated vagus nerve branch was 31 impulses/sec.
an amplitude of 7-20 μvolts; during
ulation of the gastric mucous membrane by
soln. of HCl and 1% caffeine soln. (2-3 ml
astric intubation) the frequency and amplitude
he potentials increased in 10 of 11 experiments.
In tumor-bearing rabbits initial activity was divided into 3 types. In 7 experiments initial activity was minimal, potential frequency did not exceed 10 impulses/sec. and their amplitude was hardly distinguishable from the noise of the intensifier; in 3 experiments the frequency of the impulses varied from 17-32 impulses/sec.; in 2 experiments the activity was 48 and 50 impulses/sec., resp. The av. frequency of impulse/sec. was 15 in tumor-bearing rabbits. Stimulation of electrical activity following admin. of HCl and caffeine was found in only 6 of 12 experiments, 4 of which had low initial activity. In these observations of innervation of the gastric body and part of the fundus, initial impulsation exceeded that in nerves leaving the region affected by the tumor. Afferent impulsation depended on the tumor size, e.g., at tumor diameter up to 1.5 cm (7 rabbits) frequency of impulses/sec. were 24 and at av. tumor diameter from 1.6-3.0 cm (5 rabbits) the frequency was 5.

10165 ANTIBODIES AGAINST GASTRIC PARIETAL CELLS. (Cz.) Bláha, J. (Charles U., Prague), J. Chalupský and I. Pavlásek. Vnitrni Lek. 12(12):1145-1151, 1966.

Sera from 29 patients with pernicious anemia were studied by indirect immunofluorescence for the presence of antibodies against the cytoplasm of parietal gastric cells. The formation of these antibodies is related to the occurrence of histologically diagnosed chronic atrophic gastritis; this correlation is even more pronounced if the gastritis is accompanied by pernicious anemia. The control group consisted of 15 individuals with normal or increased gastric secretion. Sections of gastric mucosa, removed by surgery from patients with duodenal ulcers, served as antigen. The sections were treated at room temperature for 30 min. with the human serum and then with fluorescein isothiocyanate-labeled goat or swine serum against human γ-globulin. To increase the contrast, the sections were subsequently stained by Evans blue. Antibodies against cytoplasmic parietal cells were detected in sera of 24 patients (82.7%) with pernicious anemia; in sera collected from individuals of the control group the antigen were not detected. Demonstration of these antigens can be used as a complementary diagnostic test for the detection of chronic atrophic gastritis in the early phase of the disease.

10166 THE INTRAOPERATIVE GASTROVIEWER AND ITS USE IN GASTRECTOMY OF SUPERFICIAL CARCINOMA. (E.) Inokuchi, K. (Kyushu U., Fukuoka, Japan) and M. Furusawa. Surgery 62(2): 255-257, 1967.

A new type of intraoperative gastroviewer is described which gives an increased and fuller view of superficial carcinoma and its margins than heretofore. The instrument consists of a sophisticated tube with a lens system that permits a 60° angle view of the mucosa. Strong light made by a lamp within the gastroviewer is conducted by glass fibers to the scope and into the stomach. Through an opening by gastrotomy, the polyethylene guide (gastroslip) is first inserted, and the surrounding tissue is tightly tied with silk thread, thereby preventing oozing of blood from the open wound and leakage of inflating air. The scope is then inserted through the guide tube, and air is pumped into the stomach to distend it. Because of the wide range of view and strong lighting, the mucosal lining can be visualized clearly and the lesion studied in detail. The extent of the carcinoma is carefully studied; by probing, the surgeon can determine the farthest margin of the lesion and mark it with a hemostatic clamp. Gastrectomy is then performed at a cutting line at least 2 cm proximal to this margin, and thus there is little likelihood of leaving any cancerous tissue in the gastric remnant. This instrument is also useful in detecting multiple lesions; often only the major lesion has been found by conventional methods and the minor lesions overlooked; however, with this instrument, the mucosal lining can be quickly and accurately examined for other smaller but vital lesions. This instrument is particularly valuable in surgery for superficial carcinoma.

10167 PROTEIN COMPOSITION OF GASTRIC JUICE AND ITS RELATION TO THE CONDITION OF THE MUCOSA IN SECRETORY INSUFFICIENCY OF THE STOMACH. (Rus.) Meleshko, V. E. (L'vov Med. Inst., USSR). Klin. Med. (Moskva) 45(5):122-131, 1967.

3 ARTERIAL ANASTOMOSES OF ILEOCECAL ANGLE
AND TERMINAL DIVISION OF ILEUM IN MAN.
) Dovgiallo, N. D. (Donets Med. Inst., USSR)
. S. Bugaeva. Arkh. Anat. 52(4):86-90, 1967.

omoses between ileocolic artery branches and
l small intestine arteries are the main
teral pathways seen at sectioning of the
olic artery and sometimes the distal small
tine arteries. In a study on 107 abdominal
ies of adult cadavers anastomoses were absent
9%, while single anastomoses were found in
, double in 50.5%, and triple in 17.7%.
anastomosis diameter was 0.1-0.4 cm, and
h 7-14 cm. Anastomosis supplied the terminal
of the ileum at the length of 10-70 cm, most
15-35 cm. First-order arcades were found
.7%, 2 in 30.9%, 3 in 7.5% and none in 14.9%.
variants of branching of vessels in the re-
of anastomosis are: (1) simple variant (16%)
to the paracolic bed of large intestine,
straight arteries and sometimes several small
es of first order; (2) variant of more com-
ted structure (27.7%), arcades of first order
ocated in the left half or somewhat closer
e ileocecal angle, sometimes second order
es were possible; a straight artery, outgoing
the last arcade approached the mesenteric end
e ileum, was reduced in diameter, and entered
all of the ileocecal angle or combined with
ast cecal artery; (3) complicated variant,
order arcades were located at the lower
hery of the anastomosis close to the ileo-
angle, there could also be arcades of second
hird order; in 50%, vessels bunch out in a
nal direction toward the cecum and ileum,
e remaining part the last straight artery
ed the ileocecal angle (56.6%). Resection
eocolic artery 2.5-6.5 cm from the ileocecal
e is recommended; for necessary mobilization
larger segment of ileum, resection could be
-2 small intestinal arteries at 7-14 cm of
th anastomosis or 15-35 cm length of intestine;
n resection should be no closer than 10-15 cm
the ileocecal angle. Venous anastomoses do
always correspond to the arterial ones.

9 INTESTINAL CYTOCHROME RESPONSE WITH
REPAIR OF IRON DEFICIENCY. (E.)
man, P. R. (Stanford U. Sch. Med., Palo Alto,
f.), P. Sunshine and Y. Leonard. Pediatrics
):863-871, 1967.

nal biopsies were obtained from 5 infant
ents by means of a Rubin tube passed with
roscopic monitoring, 24-32 hr. after an i.m.
of Fe-dextran. A higher cytochrome-oxidase
vity existed in newly produced cells at the
of the villus than in older cells which had
formed during a state of Fe deficiency.
lar phenomena have been described in the rat,
esting that the repair of intestinal cyto-
me oxidase activity is limited by the rate
ell proliferation. Colchicine, by arresting
cell division at metaphase, has been shown experimentally to interfere with cytochrome-oxidase repair when given along with Fe-dextran. Aspartate-transcarbamylase, alkaline phosphatase, sucrase and maltase, all enzymes not containing Fe or requiring it as a cofactor, showed normal activity in intestinal mucosa of the Fe-deficient rat. Intestinal malfunction was ruled out in such rats by determination of fecal-fat excretion, ^{131}I polyvinylpyrrolidone excretion as well as by the transport of glucose and galactose in everted sacs of the jejunum and ileum.

10260 ENZYMATIC ACTIVITY OF THE SMALL INTESTINE IN CHRONIC NONSPECIFIC ENTEROPATHIES. (Rum.) Fodor, O. (3rd Med. Clin., Cluj, Rumania), D. Dumitraşcu, G. Ciofu, I. Itu, S. Tragor, A. Nicoară, C. Calu and D. Grigoraş. Med. Intern. (Bucur.) 19(2):171-180, 1967.

In 70 patients with various common intestinal conditions (chronic enteritis, dyskinesia, and others) or previous stomach surgery, the enterokinase activity in the jejunal secretion av. 1827 ± 2067 Slighin U/cc and 2600 Slighin U/cc, resp., as compared to 180 ± 23 Slighin U/cc in 20 controls while the resp. alkaline phosphatase value were 34 ± 10 Bodansky U/cc and 41 ± 18 Bodansky U/cc as compared to 19 ± 8 Bodansky U/cc in controls. The av. alkaline phosphatase conc. in the fresh mucosa of patients with enteropathies or in those with stomach surgery were 6608 ± 8753 Bodansky U/cc and 7632 ± 10,097 Bodansky U/cc, resp., as compared to 4116 ± 2287 Bodansky U/cc in controls. In controls, the intestinal mucosa/intestinal juice alkaline phosphatase ratio was constant and av. 100 while in the patients studied the ratio varied greatly and av. 250 for patients with enteropathies and 200 for surgical cases. Agar-gel electrophoresis of the intestinal juice revealed 6 protein fractions, the only difference between patients and controls being in fraction V (70% and 82%, resp.). This fraction was located between the electrophoretic positions of serum α- and β-globulins, where both enterokinase and alkaline phosphatase are expected to be found. There was no relation between enzyme activity, pH, age of patient, or duration of disease. Enterokinase activity was lower in patients with diarrhea than in those without. Enzymatic activity in enteropathic patients seems to be higher than normal; however, the wide spread of the figures suggests that while digestion and intestinal absorption are correlated phenomena, they are capable of undergoing independent variations.

10261 MUCOSA OF THE SMALL INTESTINE IN PERNICIOUS ANEMIA. (E.) Foroozan, P. (VA Hosp., Madison, Wis.) and J. S. Trier. New Eng. J. Med. 277(11):553-559, 1967.

Peroral small intestinal biopsies (52), obtained serially from 8 anemic patients (5 men, 3 women; 55-83 yr. old; pretreatment hematocrit values ranged from 15-34%) with untreated pernicious anemia before and after vitamin B_{12} therapy were compared with 22 biopsies from 11 control subjects with normal hematocrit values and no known disease of the small intestine. Histologic survey revealed decreased mitosis in the crypts, shortening of villi, megaloblastosis and megalocytosis of epithelial cells and an increase in cellular elements of the lamina propria in pretreatment biopsies from all 8 patients with pernicious anemia. Quantitative evaluation of mitosis, epithelial surface length and epithelial cell nuclear size confirmed the histologic observations. After vitamin B_{12} treatment, mitosis increased rapidly to control levels. In contrast, epithelial surface length and nuclear size reverted more gradually to control levels. In contrast, epithelial surface length and nuclear size reverted more gradually to control levels. Two or more mo. after vitamin B_{12} admin., biopsies from all 8 patients were histologically indistinguishable from those of controls. Characteristic morphologic changes are thus consistently found in the mucosa of the small intestine of patients with pernicious anemia. These changes revert to normal after adequate vitamin B_{12} replacement and do not appear to cause significant clinical symptoms.

10262 ENTERITIS NECROTICANS IN UGANDA. (E.) Wright, D. H. (Makerere Univ. Coll., Kampala, Uganda) and J. P. Stanfield. *J. Pediat.* 71(2):264-268, 1967.

A report is presented of 15 cases of enteritis necroticans (nonepidemic form) among 15 children in Uganda; (mean age 4 yr., and ranging from 8 mo.-7 yr.). Male subjects predominated, 12 to 3; most were Baganda, but there were 3 from other tribes. Most cases were the acute toxic type, similar to those reported recently from New Guinea. In most cases, the illness began with mild fever and gastrointestinal symptoms, colicky central abdominal pain with vomiting and diarrhea, and later abdominal distention. After 2-3 days, the child's condition usually deteriorated rapidly with symptoms of shock and intestinal obstruction; terminally, there was often a rising temperature, increasing abdominal distention, jaundice and stupor. A neutrophilic leukocytosis was recorded in 3 and the hemoglobin level was below 7 g% in 3. Most appeared to have been well nourished. The gastrointestinal tract presented a striking and characteristic appearance with thickening and distention of the loops of the jejunum. In all cases, the mucosa of the esophagus, stomach, and first and second parts of the duodenum was normal. The mucosal lesion began abruptly either in the third part of the duodenum or the first few inches of the jejunum. The affected intestine had areas of necrosis extending for a variable distance through the wall; in 2 cases, only the superficial part of the mucosa was affected; the remainder showed deeper involvement, with necrosis extending into the muscle in 3 cases. In most cases the necrotic slough contained large numbers of ba
gram-positive cocci and gram-negative bacilli
ually predominated, but short gram-positive r
resembling *Clostridium welchii* were seen in 1
cases. Gas bubbles were observed in the intes
wall in 4 cases. *C. welchii* Type C was isolat
from the intestine and mesenteric lymph nodes
patients; 1 of these was Type A, 1 Type C and
untyped. *C. welchii* Type C was isolated from
patient who subsequently recovered. Only *Esc*
ichia coli was isolated from the intestine of
patients after death. The etiology of enteri
necroticans in Uganda is obscure; cases have
sporadic in occurrence and have not been asso
with any particular food or custom. *C. welch*
may play a role in the etiology of enteritis
necroticans in Uganda, although invasion of t
intestine with this organism may be a seconda
phenomenon rather than the primary cause of t
disease. Although it has been suggested that
ascariasis may be implicated, *Ascaris* infesta
tion was found at autopsy in only 1 of the 15
cases.

10263 TRAUMATIC INTRAMURAL HAEMATOMA OF T
DUODENUM. (E.) Webb, A. J. (Queen
Elizabeth Hosp., Birmingham, England) and J.
Taylor. *Brit. J. Surg.* 54(1):50-56, 1967.

A 10-yr.-old boy was admitted with a 2-day hi
of abdominal pain, frequent nonbilious vomiti
generalized rebound abdominal tenderness, gua
in the right hypochondrium, scanty intestinal
sounds and pelvic peritoneal irritation. Lap
omy was performed after discovery of a tender
above and to the right of the umbilicus; diag
was subserous intramural hematoma of the duod
Antibiotics, nasogastric suction, and i.v. fl
were given postoperatively, but this course w
troublesome. Large aspirations, accompanied
hypokalemia and hypochloremia, persisted for
wk. A Ba study 32 days postoperatively showe
some mural encroachment on the upper duodenal
lumen, with delay in gastric emptying. A 9-y
old boy complained of upper abdominal pain af
being hit lightly in the back by a car; after
2 days, abdominal pain increased and frequent
bilious vomiting began. At operation a norma
pendix was found with marked ileocecal and me
teric lymphadenopathy; some blood-stained per
neal fluid was found. A retroperitoneal hema
was found overlying the inferior vena cava an
third portion of the duodenum; this was an in
mural duodenal clot lying between the longitu
and circular muscle coats with a breached and
fragmented seromuscularis. Minimal retroperi
hematoma was present and no bleeding points w
found. The abdomen was closed with retroperi
neal drainage. Large bilious aspirates persi
postoperatively; he was discharged on day 21
was well 3 wk. later. The literature (5 pati
is reviewed, especially with regard to manage
Surgical intervention with evacuation of the
hematoma is preferred over conservative treatment.

4 INFANTILE PNEUMATOSIS INTESTINALIS. (E.)
Stone, H. H. (Emory U. Sch. Med., Atlanta,
. Bull. Emory Univ. Clin. 5(2):45-55, 1967.

matosis intestinalis of infancy apparently
lops as a consequence of bacterial invasion
ne intestinal wall; animal investigations and
view of all reported cases in infants yield
which support this theory. Due to a func-
al break in the mucosal barrier, bacteria
h the submucosal space; these bacteria propagate
gas collects in large cystic spaces. Because
n inadequate local blood supply, the gas
ot be absorbed as rapidly as it accumulates;
is then becomes overwhelming, and the child
, usually within a brief period of time. In
ns, the clinical course usually progresses
an episode of enterocolitis, through a stage
arked paralytic ileus, to a terminal state
is typical of either generalized sepsis or a
inating pneumonia. A successful therapeutic
men requires the admin. of effective anti-
ics and possibly the selective use of either
enal steroids or the hyperbaric O_2 chamber.
ensive, careful fluid and electrolyte therapy
necessary, in addition to all other supportive
sures.

65 NINETY-TWO CASES OF ILEOSIGMOID KNOTTING
IN UGANDA. (E.) Shepherd, J. J.
kere Univ. Coll., Kampala, Uganda). Brit. J.
g. 54(6):561-566, 1967.

rteen of the 14 females (93%) and 55 of the 78
es (70%) were from the Baganda tribe; the age
ge was from 11-75 yr., with an av. of 42 and
highest incidence was found in those aged
39 yr. Only 1 patient gave a history of pre-
us acute abdominal symptoms. Significant
senting symptoms included pain, vomiting
ich usually occurred at onset of pain), con-
pation and distention. In 73 (80%) of the
ients part of the intestine was gangrenous; in
cases either the small intestine alone, or
h the small intestine and the pelvic colon,
gangrenous, and in only 4 cases was the pelvic
lon gangrenous and the small intestine viable.
rtality rate was 50%, as 46 of 92 patients died;
nce 3 died without operation, the operative
rtality was 48%. Patients who were seen within
hr. had a mortality rate of 41%, whereas those
ming after 24 hr. had a mortality rate of 70%.
ong patients seen within 24 hr., the death rate
r those with viable intestine was higher than
r those with gangrene. While ileosigmoid knot-
ng has often been considered as a variant of
lvulus of the sigmoid colon, it is suggested
at it is more likely to be associated with ex-
ssive motility of the ileum. Development of
eosigmoid knotting has been suggested as follows:
loop of small intestine passes down the left
racolic gutter, and the small intestinal loop
rns upward to commence a clockwise knot; an
ternative anticlockwise knot may develop; the
ex of the loop enters an internal hernia; the anterior wall of the hernial orifice is the base of the loop and its mesentery; usually the small intestine becomes gangrenous first, and later the sigmoid colon. Surgical correction consists of placing clamps to that portion of the small intestine and its mesentery which constitutes the anterior wall of the internal hernia. After division, the small intestine can be gently unwound and removed. If gangrenous, the sigmoid colon is excised, the distal stump closed, and the proximal end exteriorized as a terminal colostomy. This latter procedure transforms the operation from one that is complex and lengthy to one that is simple and rapid.

10266 CHANGES IN THE INTRAMURAL NERVOUS APPARATUS OF THE DUODENUM AND DUODENAL STASIS. (Rus.) Mirzaev, A. P. (Leningrad Sanit. Hyg. Med. Inst., USSR) and M. A. Petushinov. Vestn. Khir. Grekov. 93(5):19-23, 1967.

Seven patients (3 females, 4 males; 20-54 yr. old) with the acquired form of duodenostasis (based on clinical, roentgenological and surgical data) were divided into 3 groups. In Group 1, consisting of 2 patients with moderate symptoms and duration of the disease for 3 and 7 yr., resp., and with a clinical diagnosis of cholecystitis, surgery revealed duodenostasis in the compensation stage. Upon neurohistological study, neural elements in the ganglion were slightly changed, this was basically correlated to a lesion which was reactive in character, e.g., the initial stage of reversible changes of the stimulative type. Group 2 consisted of 2 patients with pain symptoms and dyspeptic disorders and duration of disease of 6 and 19 yr., resp.; these had previously been operated upon for duodenostasis (duodenojejuno anastomosis); surgery revealed duodenostasis in the subcompensation stage; neurohistological study revealed changes which were mainly parabiotic or paranecrotic in character. Group 3 consisted of 3 patients with a pronounced clinical picture of disease and pathological processes in the stomach, gallbladder and pancreas, of up to 15 yr. duration; these had been operated upon previously, and had been diagnosed as having the decompensation stage of duodenostasis; changes in the intramural nervous apparatus had an irreversible necrotic character of Stages 2-3 in 1 patient, and Stage 3 in 2 patients. Changes included argentophilia, pyknosis, eccentric location of nuclei, protoplasmic enlargement, increase in dendrites, vacuolization, and others. A definite correlation was found between the clinical picture of duodenostasis and changes in the elements of the intramural nervous system of the duodenum, e.g., the greater the changes in neural fibers and cells of Auerbach's plexus of the duodenal wall, the greater were the anatomical changes and the more pronounced the clinical picture of the disease. Possible causes for the development of functional changes in the intramural nervous apparatus are discussed. Three case histories are given in detail.

10267 MASSIVE SMALL-BOWEL RESECTIONS. OPERATIVE AND DIETARY MANAGEMENT.

(E.) Leonard, A. S. (U. Minnesota Hosp., Minneapolis), A. S. Levine, R. Wittner, H. Buchwald and R. L. Varco. Arch. Surg. (Chicago) 95(3):429-435, 1967.

Massive small-intestinal resections were performed on 2 patients; a 41-yr.-old white male with high small-intestinal obstruction and peritonitis had massive small-intestinal resection and an ascending jejunocolostomy done, leaving 45.7 cm of proximal jejunum, while a 4-yr.-old Latin American boy with intestinal volvulus and peritonitis had only 20.3 cm of proximal jejunum remaining after resection. Each also had bilateral truncal vagotomy, pyloroplasty and gastrostomy performed. Vagotomy and pyloroplasty was done to decrease gastric hypersecretion. Postoperatively, continuous gastrostomy feedings were maintained until p.o. intake was tolerated, and initial p.o. intake of fluids was minimized by use of i.v. therapy to replace stool losses and maintenance needs. The patients were fed a high-protein, low-fat, low-carbohydrate, nonfiber-containing feeding formula which was admin. through a 24-hr. period with a constant infusion pump; this appeared to decrease diarrhea and steatorrhea, and to allow more efficient absorption, particularly during the first postoperative mo. It is believed that close adherence to these principles led to survival of the 4-yr.-old child 1 yr. after massive resection, and was responsible for a wt. gain from 26 to 32 pounds during this period. The adult patient, 2 yr. after massive resection, gained 20 pounds, from 160 to 180. Balance studies in the child showed that by 3 mo. 25%, and by 4 mo., over 50% of the fat was absorbed; increased fat absorption was further demonstrated by vitamin A and carotene levels, which increased from an av. of 20 to an av. of 50 mg/100 ml and from 24 to 34 mg/100 ml, resp., over a 4-mo. period. Similarly, prothrombin time returned to normal within the first 3 mo. N absorption increased considerably in the first 4 wk. and balance became positive by 3 mo., at which time the diet described heretofore was begun. Ca balance was preserved over the entire period of hospitalization. Special studies at 1 yr. after operation revealed cholesterol absorption to be almost absent and the serum cholesterol in the low range (130-140 mg/100 ml). Cyanocobalamine absorption was far below normal in the 2% range (Shilling test); a decreased vitamin A tolerance and decreased carotene, at 30-50% of normal, were noted. At 1 yr., xylose and folic acid absorption were normal, as were liver functions and plasma protein composition. Both patients are now maintained on a high-protein, low-fat, bland regimen, with the gastrostomy tube still in place in the child. It is concluded that the comparatively rapid stabilization of the child and his favorable anabolic state demonstrate that such children can be salvaged by adhering to these principles.

10268 PRODUCTION OF ARTIFICIAL SPHINCTERS. ABLATION OF THE LONGITUDINAL LAYER OF THE INTESTINE.

(E.) Schiller, W. R. (Northwestern U. Med. Sch., Chicago, Ill.), L. J. A DiDio and M. C. Anderson. Arch. Surg. (Chica 95(3):436-442, 1967.

Resection of the small intestine was performe in normal mongrel dogs; the length of intesti from the main pancreatic duct to the ileoceca junction was measured, and in 12 dogs the dis 75% was resected, leaving approx. 4 inches of terminal ileum and the ileocecal area intact; in 25 dogs, 90% of the small intestine was re leaving approx. 2 inches of proximal jejunum, inches of terminal ileum and the duodenum int Intestinal continuity was restored with an op 1-layer anastomosis. Animals with either typ resection were then divided into 4 groups: G 1 served as controls; in Group 2, an isoperis segment measuring 3-4 inches in length was co structed in the remaining distal jejunum; Gro was similar to Group 2, except that the isola jejunal segment was reversed (antiperistaltic and in Group 4, intestinal resection was foll by the circumferential removal of 1-cm strips longitudinal muscle, except for the part of t layer which was covered by mesentery; the und lying circular (closing) component was thus f to contract unopposed; 2 of these artificial sphincters were placed 3-4 inches proximal to the jejunoileal anastomosis. A 90% resection was associated with a high mortality, whereas could adjust to loss of 75% of the lower smal intestine. Interpolation of isoperistaltic se ments did not improve results. Some animals with antiperistaltic segments interposed into the intestinal stream sustained a wt. loss wh was less than controls; however, there was a rate of complications in this group, includin obstruction and anastomotic disruption. Remo of 1-cm segments of longitudinal muscle produ a short segment of intestine with a sphincter action; these artificial sphincters not only a peared to increase survival time and reduce w loss, but also were associated with no risk o obstruction or disruption. Several animals su vived for extended intervals when these sphin were used after 90% intestinal resection. Mic roscopic studies showed that the myenteric (ne vous) plexus was removed along with the longitudinal muscle, but the segments did not appea to be as spastic as the aganglionic segment described for congenital megacolon. The techn feasibility of this procedure in the human has been shown, and clinical evaluation of this me of slowing transit seems warranted in patients with severe motility problems.

10269 THE SURGICAL AND METABOLIC ASPECTS O MASSIVE SMALL BOWEL RESECTION IN THE NEWBORN.

(E.) Benson, C. D. (Child. Hosp. Michigan, Detroit), J. R. Lloyd and K. L. Krabbenhoft. J. Pediat. Surg. 2(3):227-240, 1

A 5-yr. study of 10 newborns who had undergone extensive small intestine resection (some in excess of 50%) included fecal recoverability

^{131}I-tagged triglycerides, free fatty acids
d radioactive iodinated serum albumin as well
X-ray examination for bone age, Schilling tests,
neradiofluoroscopy and routine upper gastro-
testinal studies. Height and wt. was recorded
regular intervals and routine excretion studies
ployed Silver's method. In the early postopera-
ve period there was a serious inability to ab-
rb dietary fats and a lesser inability to ab-
rb protein. Carbohydrate tests gave results
thin normal limits. Bone age tests resulted in
lues within the normal range in all but 1 pa-
ent. Schilling tests on 3 of the older chil-
en produced results within the acceptable range.
e compensatory mechanism of the human body can
intain an adequate nutritional state with but
-35 cm of small intestine remaining after re-
ction, provided that the ileocecal valve is in-
ct. It is probable that there is an increase in
liber of the intestine along with an increased
porization of the villi and deepening of the
tervillous crypts. It is postulated that there
also some increase in length of the intestinal
mnant. At the termination of the study 8 of
e 10 patients were alive and well; the 2 who
ed had ruptured umbilical cord hernias. Re-
ction in both instances had included the ter-
nal ileum and ileocecal valve. It is concluded
at a minimum of 25-30 cm of small intestine plus
e ileocecal valve is sufficient for continued
trition and growth in the newborn. Attention
ward a better understanding of the physiologic
tential of the remnant is suggested.

270 EFFECT OF ARTIFICIAL COLLATERAL BLOOD SUPPLY UPON INTESTINAL AUTOGRAFT.
us.) Berlin, L. B. (Kirov Order of Lenin Med.
st., Leningrad, USSR) and V. F. Zhupan. Arkh.
at. 52(7):93-96, 1967.

each of 20 dogs 2 segments of the small in-
stine were taken (12-16 cm length) with vascular
anches consisting of 1 artery and an analogous
in; the continuity of the intestine was restored
end-to-end anastomosis. On each side of the
dominal wall incisions were made of s.c. pouches,
ing the length of intestinal transplants; the
ft transplant was incised transversely every cm
tween large vascular ramuli to submucous layers
d placed into the left s.c. pouch, while the
ght transplant without incisions and fixed in
e right pouch served as a control. The abdominal
vity was sewn; 1 end of both transplants sewn
to the s.c. bed, and the other brought out
rough special cutaneous incisions of the ab-
minal wall and sutured to the ends of the
taneous wounds. Ligation of vascular branches
s performed 5-60 days after transplantation.
e development of collateral blood supply of the
testinal transplant, grafted under the skin,
curred faster if stimulated by incisions of
e serous and muscular membranes and if ligation
the vascular branch was performed at a later
riod. Incisions of the intestinal wall stimu-
ted formation of vascular bonds of transplants
th surrounding tissue, showing a way toward improvement of blood supply to the grafted intestinal segment. In almost all the cases inflammatory, dystrophic and necrobiotic changes of focal character of the intestinal wall were noted. They were difficult to correlate directly with the time of vascular branch ligation and degree of collateral blood supply development.

10271 EXPERIMENTAL INVESTIGATIONS ON IMPROVEMENT OF INTESTINAL ABSORPTION IN DOGS SUBJECTED TO MASSIVE RESECTION OF THE SMALL INTESTINE COMBINED WITH USE OF THE ONLAY REVERSED SEGMENT OF THE INTESTINE. (E.) Sadowski, J. (Warsaw Med. Acad., Poland). Bull. Pol. Med. Sci. Hist. 10(2):85-92, 1967.

Ten dogs were divided into 2 groups of 5 each. Animals in the first group were subjected to resection of 66-75% of the small intestine; the animals became extremely emaciated and loss of wt. 2-3 mo. after resection amounted to 22-31% of the initial wt. The percentage of H_2O content in fecal solids was increased, and absorption of fat and protein was decreased, especially when they were placed on a high fat diet. Transit time of Ba after massive resection was shortened by 21-46%, as compared with nonoperated animals. The dogs were then subjected to a second operation, establishment of an onlay reversed segment taken from the terminal intestine; these animals regained their initial wt. 4-5 mo. after the second operation, and some exceeded their initial wt. There was improved absorption of fat and protein in comparison to preoperative values; this was observed during both a basic diet and a high fat diet. Radiological examination revealed a delay of the transit time of Ba, as compared to preoperative values, or slightly higher values than in nonoperated animals. No complications or side-effects were encountered after construction of the onlay reversed segment. Dogs of the second group were subjected to massive resection of the small intestine (the distal portion, whereas those in the first group had the proximal portion resected) combined with construction of the onlay reversed segment. There was an improvement in wt., and similar results to those obtained with animals in the first group. It is concluded that use of the onlay reversed segment improved intestinal absorption in dogs subjected to massive small intestinal resection.

10272 ROLE OF RECIRCULATING LOOPS IN THE MANAGEMENT OF MASSIVE RESECTION OF THE SMALL INTESTINE. (E.) Budding, J. (Christ Hosp. Inst. Med. Res., Cincinnati, Ohio) and C. C. Smith. Surg. Gynec. Obstet. 125(2):243-249, 1967.

A total of 54 young, healthy adult beagle dogs of both sexes were divided into 6 groups. In Group 1, the 6 dogs served as controls; 3 underwent a sham operation in the form of an exploratory laparotomy. In Groups 2-6, dogs underwent a 90% resection of the small intestine, with rearrangement of the remaining portion as a recirculating loop, including progressively more complicated procedures which required an increase in the number of intestinal anastomoses. In some dogs, 0.5 g of sodium taurocholate was added to a test meal to determine its effect upon absorption. The operative mortality rate increased as the number of anastomoses and complexity of the surgical procedure increased. The av. max. uptake for dogs in all groups during the preoperative control period varied from 14-18%; absorption was not affected by the sham operation. There was a significant postoperative decrease in fat absorption in dogs that had undergone resection; it dropped further after the first mo. and then leveled off. The addition of sodium taurocholate to the test meal had no predictable effect upon absorption. Blood chemistry was essentially normal in all groups. Neither controls nor animals that had undergone sham operation showed significant changes in gastric emptying time. In animals that underwent resection, the gastric emptying time increased from preoperative av. of from 2 hr. to 5-6 hr. postoperatively. The complexity of the operation was not related to the increase in gastric emptying time. Animals with the simplest operative procedure and least number of anastomoses survived longer and maintained their wt. better than those with more complex procedures and more anastomoses. In all dogs with resection, the results of varying degrees of malnutrition were evident. While animals with the simplest procedure (which consisted of a 90% resection of the small intestine including the ileocecal region, and insertion of a 5-cm long reversed segment of ileum end-to-end between the distal part of the small intestine and colon) gave the best results, there were several cases of serious complications; 5 died of obstruction, 2 of phytobezoars and 3 of volvulus. It is suggested that clinical application of corrective surgical procedures in the treatment of massive resection of the small intestine appears to be justified only when dietary and medicinal measures fail to maintain the patient in satisfactory condition.

10273 SINGLE-LAYER OPEN GASTROINTESTINAL ANASTOMOSIS. (E.) Bronwell, A. W. (Methodist Hosp., Lubbock, Tex.), R. Rutledge and M. L. Dalton, Jr. Ann. Surg. 165(6):925-932, 1967.

A study of 327 patients is presented in which single-layer and multiple-layer closures are compared; there were 136 colon anastomoses (95 single-layer and 41 multiple-layer), and 191 gastrojejunal anastomoses (89 single-layer and 102 multiple-layer). In anastomoses at both sites, patients with single-layer closures tolerated food and passed flatus and stool 24 hr. earlier than those with multiple-layer closures. There were no anastomotic leaks and no deaths in the single-layer series. In the multiple-layer anastomoses of the colon, 3 patients had leaks at the anastomotic site and 1 died. None of the multiple-layer closures of the gastrojejunal region leaked. It is concluded that single-layer anastomoses can be accomplished with less morbidity and with comparable mortality to multiple-layer closures. In comparison to results of this study, a survey of more than 300 American surgeons showed that most preferred 2-layer closures for both colonic and gastric operations.

10274 REAPPRAISAL OF OPEN INTESTINAL ANASTOMOSES. (E.) Hamilton, J. E. (U. Louisville Sch. Med., Ky.). Ann. Surg. 165(6):917-924, 1967.

Four types of open intestinal anastomoses were performed on 29 healthy mongrel dogs: (1) Stand the double-row inverting anastomosis; (2) Halste or single-row inverting stitch in which the need theoretically catches the submucosa only; (3) Navy, a 1-row through-and-through everting intestinal anastomosis; and (4) the modified Gambee, a 1-layer through-and-through inverting stitch. Anastomoses were done in tandem in the terminal ileum, the first located 6 inches above the cecu and the others each 5 inches proximal to the preceding and with rotation of position from dog tc dog; usually, all 4 methods were performed in the same animal. Analysis of gross anastomotic defects showed that Gambee and Navy each had 3 small defects sealed by adhesions, Standard had 4 defects, and Halsted had 1, a disruption of tl anastomosis and fatal peritonitis. The Navy method showed fewer adhesions than the Standard; and the Gambee had considerably fewer adhesions than the Standard, and slightly more than the Halsted method. Edema and inflammation of the suture line were far more pronounced in the Standard and Halsted technics than in the Gambe and Navy technics; all changes were most pronounced in the Standard, which also showed some areas of avascular necrosis. A study of the lu narrowing by the inverted anastomotic flange showed, by gross estimate, an av. of 54% for th Standard, 39% for the Halsted, 4% for the Gambe and 3% for the Navy technic. The Standard anastomosis av. 29 min. operating time, the Halsted 18 min., the Gambee 21 min. and the Navy 14 min By the air-inflation-leak test, the 4 methods w compared in 3 ways: last to leak, av. leak pre sure and % of each method not leaking under 50 Hg. Tests taken immediately after completion o anastomosis showed the Standard technic to be t strongest, and the Navy least secure; there was little difference between the Gambee and Halste During the crucial healing period from the thir to the sixth day, the Gambee was slightly weake throughout than the Halsted anastomosis, but stronger than the Standard; the Navy was by far the weakest of the 4 anastomoses. Two Standard and 5 Navy anastomoses, without obvious defect, leaked at pressures of 40 mm Hg or less. On th basis of these animal experiments and limited clinical experience (113 procedures), it is concluded that the Gambee method is superior to th other anastomoses tested, and is the procedure of choice in open intestinal anastomoses.

75 TRANSMESENTERIC PLICATION FOR SMALL INTESTINAL OBSTRUCTION. (E.) Ferguson,
T., V. A. Reihmer and M. R. Gaspar. Amer. J.
g. 114(2):203-208, 1967.

eport is presented of the use of transmesenteric cation in 12 patients; 11 had acute small intinal obstruction and 1 had intermittent small estinal obstruction. A total of 33 previous iotomies had been performed in these 12 pants; in 1 patient with chronic obstruction, 10 or operations had been performed. The imiate postoperative course was uneventful in all ients; all tolerated fluid well on the fourth toperative day. A pelvic abscess developed in atient 3 wk. after operation and was drained nsvaginally. Obstruction recurred in 1 patient had the 10 previous operations for small intinal obstruction; plication was not used in air of this recurrence. Ten of the 12 pants had no further episodes of abdominal pain /or intestinal obstruction; in addition to the ase of recurrence of obstruction, 1 patient erienced mild postprandial pain for the first after operation. Thus, 10 of 12 patients foled for 2 mo.-5 yr. had an excellent result, another had a good result. Transmesenteric cation is a simple, rapid operation for the vention of small intestinal obstruction. Reery is rapid after the procedure and significant toperative ileus was not encountered. The of absorbable suture is not recommended and have been responsible for the 1 case of rerent obstruction in this series. It is advised t this procedure be used for recurrent intesal obstruction and should be considered when ietal or visceral peritoneal denuding has urred secondary to enterolysis or extensive rative procedures.

10335 ABBREVIATED HISTALOG GASTRIC ANALYSIS. COMPARISON WITH PEAK ACID OUTPUT. (E.) Castell, D. O. (U.S. Naval Hosp., Bethesda, Md.), R. B. Johnson and H. A. Sparks. Amer. J. Dig. Dis. 12(7):713-719, 1967.

A total of 79 patients were subdivided into an ulcer group and a control group. The ulcer group included 37 patients (34 males, 3 females), with a mean age of 41 yr.; these had definite radiologic evidence of duodenal ulcer. In the control group there were 42 patients (37 males, 5 females), with a mean age of 43 yr.; this included patients with gastrointestinal complaints in whom X-ray study had given negative results, and also patients without gastrointestinal symptoms. Peak acid output after betazole (100 mg) stimulation during a standard gastric analysis was obtained in each patient, and the results were compared with the 30-min. acid output obtained in the same patient during the abbreviated gastric analysis performed by collecting gastric juice only during the interval from 45-75 min. after betazole (100 mg) stimulation. In controls, the mean value for peak acid output was 10.97 mEq/30 min., and the mean value for the abbreviated test was 8.44 mEq/30 min. For the 37 ulcer patients, the mean values were 16.27 and 12.35 mEq/30 min. for the standard gastric analysis and the abbreviated test, resp. During the abbreviated gastric analysis, 18 ulcer patients (49%) and only 6 controls (14%) had an acid output greater than 13.41 mEq/30 min.; also, 21 controls (50%) and only 7 ulcer patients (19%) had an acid output less than 7.68 mEq/30 min. A striking degree of overlap between the ulcer and control groups was shown by both procedures. The limitations of gastric analysis as a diagnostic tool for the differentiation of ulcer and nonulcer patients is again emphasized since, in 32.9% of the subjects, incorrect diagnoses were drawn from results of both methods of gastric analysis. It is concluded that the shorter and more tolerable abbreviated gastric analysis may be as useful as the standard gastric analysis (peak acids) in evaluating the individual patient's secretory potential.

10336 BENIGN GASTRIC ULCER WITH LIFE-THREATENING HEMORRHAGE. (E.) Stafford, E. S. (Johns Hopkins U. Sch. Med., Baltimore, Md.), W. F. Ballinger, II, G. D. Zuidema and J. L. Cameron. Ann. Surg. 165(6):967-976, 1967.

In a series of 239 patients operated upon for benign gastric ulcers, 116 were bleeders, and 66 (57%) of these were uncontrollable bleeders. Of 203 patients under age 70, 92 (45%) bled; of these, 52 bled uncontrollably and 8 died after operation (15%). There were 36 aged 70 or over, of whom 24 were bleeding (67%); among the latter, 14 bled uncontrollably and 6 (43%) died. There were 49 patients (21%) in the series who bled on 1 or more occasions before hospitalization during which operation was performed; of these, 21 (4
bled uncontrollably on this admission. Of 190
patients who had never bled before, 45 (24%) we
admitted with uncontrollable bleeding on this
occasion. Of the 239 patients, there were 151
men and 88 women; of 66 with uncontrollable
bleeding, there was only 1 woman among 14
patients who died in the hospital after operat
When considered from a socioeconomic standpoin
there were more who were bleeding among ward
patients (75 of 126) than among private patien
(41 of 113 or 36%). Furthermore, there were 4
ward patients (69%) and only 21 private patien
(32%) among the 66 who were bleeding uncontrol
Nearly half (28) of 66 patients with uncontrol
bleeding had significant coexisting disease,
including esophageal hiatal hernia in 7, urolo
disease in 4, arthritis in 4, cardiovascular
disease, cirrhosis of the liver, psychosis and
pulmonary disease in 3 each, and diabetes and
severe trauma in 1 each. All 66 patients with
uncontrollable bleeding received large amounts
of blood after surgery; of 52 survivors, 20
received 3 or more liters, but of 14 who died,
10 received 3 or more liters. Most gastric
ulcers were found in the prepyloric area or al
the lesser curvature, but there were 7 among 6
with uncontrollable bleeding whose ulcers were
located in the upper stomach; 6 of these 7 had
postoperative complications, and 4 (57%) expir
in the hospital. Of the 66 with uncontrollabl
bleeding, surgical procedures included 44 part
gastrectomies (vagectomy included in 8); among
these, there were 9 postoperative, in-hospital
deaths. Excision of the ulcer was done 13 tim
including 5 accompanied by pyloroplasty and 4
accompanied by pyloroplasty and vagotomy; ther
were 2 deaths in this group. One of 2 patient
treated by sleeve resection alone died. Four
underwent ligation of a bleeding vessel in the
base of the gastric ulcer combined with pyloro
plasty and vagectomy; 1 of these died. Two
patients were treated by gastrojejunostomy and
vagectomy, and 1 died. Fourteen of 66 died, f
a mortality rate of 21%, compared with a
mortality rate of 3% in 173 patients with gastric ulcer operated upon for all reasons other
than uncontrollable hemorrhage. Of 14 patient
70 or more yr. of age, with uncontrollable
bleeding, there were 8 men and 6 women; 6 of
men (75%), and no women died. Of 46 of the 6
patients with uncontrollable bleeding availabl
for long-term evaluation, 30 (65%) were considered to have excellent results subsequent t
operation, and 16 (35%) had a poor result
initially, although 4 of these subsequently
became asymptomatic; thus, at time of report,
(74%) were asymptomatic and had resumed normal
activities.

10337 VALUE OF VARIOUS GASTRIC SECRETION TESTS IN RELATION TO SURGICAL TREAT-
MENT OF GASTRODUODENAL ULCER. (It.) Mercati,
(U. Perugia, Italy), P. Furiosi and F. Pasqui
Gazz. Int. Med. Chir. 72(11):936-949, 1967.

ults of 3 gastric secretion tests performed
chronological succession were evaluated in 82
er patients (28 gastric; 54 duodenal) and in
normal controls. The following tests were
formed: (1) nocturnal gastric secretion
ording to a modified Levin-Kirsner-Sundweiss
hod (samples obtained every 60 min.); (2)
mented histamine test according to Kay (0.04
kg of histamine HCl with sampling every 15 min.
l hr.); (3) insulin stimulation test accord-
to Hollander (15 U of insulin followed by
pling every 15 min. between 30 and 90 min.).
al nocturnal gastric secretion (over a 12-hr.
iod), vol./hr., and av. HCl conc. was 350 ml,
ml, and 24 mEq/liter, resp., in controls,
compared to 580 ml more than 40 ml, and 57
/liter, resp., in 70% of duodenal ulcer
ents; 350 ml, 0, and 45 mEq/liter, resp., in
remaining 30% of ulcer patients; 310 ml, 0,
30 mEq/liter, resp., in gastric ulcer
ents. Augmented histamine secretion and max.
output was 180 ml and 19 mEq/hr., resp., in
rols as compared to 250 ml and over 40
/hr. resp., in 70% of duodenal ulcer patients;
ml and 50 mEq/hr., resp., in the other 30%;
ml and 35 mEq/hr., resp., in gastric ulcer
ents. No increase in the vol. (av. 55 ml)
gastric secretion or in HCl conc. was observed
of 10 controls following insulin stimulation;
ng the 70% group of duodenal ulcer patients,
showed no increase after insulin stimulation,
le others showed marked increase in gastric
retion (70-100 ml) and high free HCl conc.
mEq/liter); an increase in HCl conc. was
ed in the 30% group of duodenal ulcer patients
er insulin. Gastric ulcer patients also
wed an increase in HCl secretion after insulin.
hough the results are not probative from a
ictly diagnostic point of view, a relation-
does exist between the state of gastric
retion and the surgical procedure which is
indicated.

8 PNEUMOCONIOSIS, EMPHYSEMA AND PEPTIC
ULCER. (Cz.) Vrána, J. (Palacky U.,
mouc, Czechoslovakia), R. Útata and V.
ička. Vnitrni Lek. 12(12):1203-1209, 1966.

incidence of gastroduodenal ulcers in 1304
ients treated for pneumoconiosis was estimated.
the total, 268 showed symptoms of mild and
of severe obstructive emphysema. Gastro-
denal ulcers were found in 5.7, 5.9, and 5.5%
patients without symptoms, with mild symptoms,
with severe symptoms of obstructive emphy-
a, resp. Differences were not observed in
production and acidity of gastric juice
lected from those with pneumoconiosis com-
cated by obstructive emphysema and from
lthy individuals. Similarly, differences
e not found when gastric juice collected from
ients with gastroduodenal ulcers was compared
h that collected from patients with ulcers
pneumoconiosis complicated by obstructive
hysema. The present study failed to contri-
e evidence for the suggested higher incidence
of gastroduodenal ulcers in patients with obstructive emphysema.

10339 DEATHS FROM PERFORATED PEPTIC ULCER. A SURVEY OF 633 CASES IN THE WEST OF SCOTLAND. (E.) MacKay, C. (Western Infirm., Glasgow, Scotland). Scand. J. Gastroent. 1(4): 299-305, 1966.

From 1954 to 1963 there was an 11.8% increase in the fatality rate from perforated peptic ulcer, according to a survey including all hospitals which accept medical and surgical emergencies in Glasgow, the counties of Argyll, Dunbarton, Lanark, and Renfrew; the area in West Scotland represents about 2.2 million persons. The fatality increase is believed due to the increasing (statistical) age of patients. Female mortality was 18.0% and male was 10.8%. Most deaths occurred in February, and between midnight and 4 a.m; delay in surgical intervention increased the rate. The perforated gastric ulcer fatality rate was 26.1%, the rate for perforated pyloroduodenal ulcer 10.4%, and stomal 15.1%. Only cases confirmed at operation or autopsy were included in the survey. Conservatively-treated cases were not included. The survey technic was that of Illingworth et al. (1944) and Jamieson (1955). The high fatality rate for perforations at the gastric site was almost evenly divided according to sex: males 25.8% and females 26.5%. Pyloroduodenal perforation fatality was lower in males (9.6%) than in females (15.7%). The sex differences may be due to age differences among those studied: the mean age for males with pyloroduodenal perforation was 45.6 yr., and 49.6 for females; male mean age in gastric perforation was 50.8, and females 51.9.

10340 VAGOTOMY-PYLOROPLASTY FOR DUODENAL ULCER: A CRITICAL APPRAISAL OF EARLY RESULTS. (E.) Herrington, J. L., Jr. (Edwards-Eve Clin., Nashville, Tenn.). Surgery 61(5): 698-704, 1967.

A report is made of the results of this procedure on 101 patients, 15 of whom were followed for 6-8 yr. and 86 of whom had been under observation for 2-5 yr. The av. follow-up was 3.5 yr. Patients consisted of 72 men and 29 women with an age range of from 22-84 yr., the av. age being 52.5 yr. In this series the operative mortality was 5%, due to the poor condition of the majority of the patients and to the presence of associated disease. The incidence of recurrent ulceration was 7.3% over a relatively short follow-up period. At present 53% are symptom-free: 30% have minor postoperative complaints. It is concluded that vagotomy-pyloroplasty is not the operation of choice for complications of duodenal ulcer. It should be recommended only for poor risk patients and where time and technical considerations preclude an operation of greater magnitude.

10341 ELECTIVE OPERATIONS PERFORMED FOR DUODENAL ULCER, WITH THEIR MORTALITY. RESULTS OF A SECOND SURVEY IN SELECTED OHIO HOSPITALS BY THE SURVEY COMMITTEE, OHIO CHAPTER, AMERICAN COLLEGE OF SURGEONS.

(E.) Hoerr, S. O., Chairman (Cleveland Clin., Ohio). Amer. J. Surg. 114(3):427-430, 1967.

This second survey was designed to study the frequencies with which 6 standard surgical procedures were electively used for chronic duodenal ulcer, and their mortality, and to compare them with the frequencies and the mortality in the first survey. These procedures were gastrectomy, gastrojejunostomy and pyloroplasty, each with or without vagotomy. Data were obtained in 35 Ohio hospitals of 6259 patients operated on between 1957 and 1966 in 15 communities; the hospitals ranged in size from 150-943 beds and were situated in communities ranging in size from a population of 9,000 to a million or more persons. The overall mortality of 2.6% represented a reduction from the overall mortality of 4.3% in the first survey. A smaller number of gastric resections and a larger number of drainage procedures were performed in the period of the second survey than during the first. Each procedure, with its mortality, was as follows: gastrectomy, 2,206 patients, 77 deaths (3.5%); gastrectomy and vagotomy, 1,732 patients, 41 deaths (2.4%); pyloroplasty and vagotomy, 1,561 patients, 19 deaths (1.2%); gastrojejunostomy and vagotomy, 496 patients, 9 deaths (1.8%); pyloroplasty only, 70 patients, 3 deaths, (4.3%); and gastrojejunostomy only, 194 patients, 11 deaths (5.7%). A great majority (77%) of operations were performed by qualified surgeons, and only 2% were performed by so-called unqualified surgeons; the mortality of patients operated on by the former (2.3%) was lower than that of patients operated on either by residents (3.5%) or by unqualified surgeons (3.8%). These findings were in contrast to those of the first study, in which the experience of the surgeon did not appear to exert a significant influence. The size of the hospital, the size of the community and whether the hospital had a closed or an open staff did not seem to affect the overall mortality. Gastrectomy with or without vagotomy had a significantly greater mortality (3%) than the drainage procedures with or without vagotomy (1.8%).

10342 RESULTS OF TREATMENT OF ONE THOUSAND PATIENTS WITH PERFORATED GASTRODUODENAL ULCER.

(Bul.) Stoianov, A. Khirurgiia (Sofia) 20(2):100-106, 1967.

Of 1012 patients treated from 1954-64, 1000 had perforated gastric (426) and duodenal (574) ulcer while 12 had perforation due to gastric cancer. Of 1000 patients (938 males, 62 females; age 20-over 70 yr.), suturing was performed in 930, (93%) with death in 64, (69%) while 70, (7%) were treated by resection, 3 (4.2%) died. Av. mortality in 11 yr. was 6.7%. The outcome of surgery does not depend on the method, but on the time lapse between perforation and surgery Surgery within the first hr. after perforation was performed in 485 (48.5%) of whom 22 (32.9% died; from 1-6 hr. after perforation in 437 (43.7%) of whom 33 (49.2%) died; 6 hr. after perforation in 78 (7.8%) of whom 12 (17.9%) di Of 67 dead, 56 died from peritonitis and paralytic ileus, 4 from emboli of pulmonary arteri 4 developed hemorrhaging ulcer in the postsurgical period, 3 from pulmonary complication (active tuberculosis in 1). On day 1 after surgery 13 died; in general, by day 1-2 after surgery 22 died (32.8%). Cleaning and washing of the abdomen is recommended; if necessary th small intestine contents should be removed during surgery by means of temporary enterotomy. Results of 1250 patients treated during 1947-1 are used for comparison.

10343 PLANTAGLUCIDE TREATMENT OF PATIENTS WITH GASTRITIS, ULCER DISEASE OF THE STOMACH AND DUODENUM.

(Rus.) Podval'niukova, T. F. (Kiev Med. Inst., USSR). Vrach. Delo (4 142-144, 1967.

Plantaglucide (a Plantago major leaf extract; admin. p.o., 1 tablet 3 times a day for 3 wk.) was given to 76 patients (66 males, 10 females 17-60 yr. old), 21 of whom had gastric ulcers, 42 of whom had duodenal ulcers, and 13 of whom had chronic gastritis during the period of exacerbation. It was most effective in those patients with reduced and normal secretory and acid-forming gastric function; it was slightly effective in patients with markedly increased acidity of the gastric juice, and not effectiv in patients with complicated peptic ulcers. Complicated peptic ulcers were found in 8 patients, and 18 had peptic ulcers combined wi secondary chronic liver and bile tract disease By day 5-7 of treatment (in most of the patien pain, dyspeptic symptoms and tympanites disappeared, stool was normalized and appetite improved. At the end of 3 wk. of treatment, protective muscular tension of the anterior abdominal wall and local painfulness disappear the general condition markedly improved, hepatomegaly was reduced in 8 of 18 and was less painful in 13 of 18; both clinically and radio logically, spastic symptoms and pain in the large intestine stopped. Essential changes of the urine and blood, as well as antitoxic and prothromoin-forming function of the liver, wer not evident. Latent gastric hemorrhages terminated in all of the patients. The quanti and acidity of the gastric content increased with a tendency toward normalization only in t patients (21) who demonstrated reduced values before treatment; bile showed some decrease in inflammatory elements. Of 54 patients with gastric and duodenal niche, the latter disappe in 25 and was reduced in size in 24; in most o the patients there was a simultaneous decrease in the swelling of the mucous membrane plica, gastric tonus, disappearance of spasms of the pylorus and improvement of Ba evacuation from stomach; symptoms of duodenitis were less ounced. Plantaglucid was well tolerated, did not induce any side effects.

10391 AN EPIDEMIOLOGICAL STUDY OF ULCERATIVE COLITIS AND REGIONAL ENTERITIS AMONG ADULTS IN BALTIMORE. I. HOSPITAL INCIDENCE AND PREVALENCE, 1960 TO 1963. (E.) Monk, M. (Johns Hopkins U. Sch. Hyg., Baltimore, Md.), A. I. Mendeloff, C. I. Siegel and A. Lilienfeld. Gastroenterology 53(2):198-210, 1967.

Information was obtained about all Baltimore, Maryland area residents aged 20 yr. or more with ulcerative colitis, regional enteritis or ulcerative proctitis hospitalized during the 39-mo. period October 1960-December 1963. On the basis of hospital record information, gastroenterologists confirmed the diagnoses of these diseases. Av. annual prevalence rates, based on total hospital admissions for these diseases and on 1960 United States census data, were calculated for specific age, sex, and color groups; prevalence rates for Jews and Gentiles were based on population estimates from a marketing survey of the Baltimore area. Incidence rates, for patients hospitalized for these diseases for the first time during the study period, were determined for the same groups. Hospital incidence and prevalence rates for both ulcerative colitis and regional enteritis were higher for Jews than Gentiles and for whites than for nonwhites. The female incidence and prevalence rates for ulcerative colitis were higher than male rates, but the sex difference was reversed for regional enteritis. Younger males and middle-aged females had somewhat higher rates for ulcerative colitis than men and women in other age groups, but no age pattern was evident in regional enteritis. For both diseases, incidence rates for persons 50 yr. and older were not markedly lower than those for younger people. After comparison of these hospital incidence rates with those from other countries, it was concluded that this hospital data gave a fairly accurate estimate of total community incidence. Further analysis of the data made it seem unlikely that diagnostic prejudice and differential likelihood of hospitalization for the groups studied could account for all of the difference in rates between whites and nonwhites and between Jews and Gentiles.

10392 SURGICAL TREATMENT OF REGIONAL ENTERITIS. (E.) Colcock, B. P. (Lahey Clin. Found., Boston, Mass.). Amer. J. Surg. 114(3):398-401, 1967.

A total of 375 patients were operated upon for regional enteritis at Lahey Clinic up to June 1963; ages were 10-79 yr. old; sex distribution was approx. equal, but more women than men required repeat surgery. The main presenting symptoms were pain and diarrhea, very frequently associated with a palpable abdominal mass. Skip areas were found in 15-18% of the patients. Of 85 operated upon during the last 5-yr. period, 8.2% had ulcerative colitis in addition to enteritis, and another 8.2% had duodenal ulcer;
17% of the patients had associated anorectal
lesions, such as fissures, fistulas or abscess
In the last group of 85 patients, 74 had Ba X-
studies, and in 97.2% there was evidence of sma
intestinal disease; 24 of 74 had the character
string sign in the terminal ileum. Indication
for surgery included an acute onset, resemblin
appendicitis, and a chronic form of onset, non-
responsive to medical treatment. Resection wa
the procedure of choice for patients with chro
regional enteritis requiring surgery, with an
end-to-end anastomosis the preference of the a
Five patients who had a bypass procedure all r
quired resection because of recurrent or persi
symptoms. In the group of 85 patients operate
upon during the last 5-yr. period, there was 1
postoperative death in a young girl who had re-
moval of the colon for ulcerative colitis and
several previous resections for small intestin
fistulas; there were no deaths after surgery p
formed for regional enteritis alone for more t
10 yr. Morbidity after surgery also was low;
temporary cutaneous fistulas developed in 4 pa-
tients after resection but all healed spontaneously; 2 patients required incision and
drainage for an abdominal abscess. Within a 5-
yr. follow-up period, 25% (78) of 312 of the p
tients required reoperation; the other 75% are
either free of symptoms or have mild symptoms
that are well controlled by conservative thera

10393 WHITE BLOOD CELL COUNT IN REGIONAL ENTERITIS. REPORT OF TWO CASES. (E.
Smith, M. P. (Swedish Hosp. Med. Ctr., Seattle,
Wash.). J.A.M.A. 201(11):890, 1967.

A 53-yr.-old woman presented with possible acu
appendicitis; before surgery, her WBC count wa
13,000/mm^3, with a differential count of 55 po
morphonuclear WBC, 6 monocytes and 39 lymphocy
some of which appeared atypical. At laparotom
a 12-inch segment of terminal ileum exhibited
the changes of regional enteritis; since the
proximal end of intestine was not obstructed t
involved segment was not resected and the pati
recovered satisfactorily. A 63-yr.-old white
presented with acute intestinal obstruction of
the lower jejunum; the initial WBC count was
5200/mm^3, with a differential count of 41 polymorphonuclear WBC, 16 stab cells, 7 eosinophil
14 monocytes and 22 lymphocytes, some of which
were atypical; on the second day, the WBC coun
had decreased to 4000/mm^3, with a differential
count of 50 polymorphonuclear WBC, 6 stab cell
6 eosinophils, 20 monocytes and 18 lymphocytes.
Laparotomy revealed changes of regional enteri
in the distal half of the small intestine; no
pass or resection of the intestine was made si
the proximal half of the small intestine was n
mal and undilated. The patient had mild diarr
for 3 mo. postoperatively. Review of 29 cases
of regional enteritis admitted in 1965 showed
11 had a blood smear that contained atypical
lymphocytes and an increased number of monocyt

is type of smear was not seen in those patients th an elevated WBC count accompanying a fistula severe intestinal obstruction, but it was seen some patients with recurrent disease. It is stulated that an inflamed intestine allows entry viruses into the body which in turn produce anges in the blood picture.

394 THE DIAGNOSIS OF CROHN'S DISEASE OF THE COLON. A CLINICO-PATHOLOGICAL
UDY. (E.) Schofield, P. F. (Manchester Roy. firm., England) and H. Fox. Brit. J. Surg. (4):307-311, 1967.

lonic inflammatory disease (75 cases) and anal ceration (1) are reviewed. Patients were clasfied into 2 groups: those with ileal disease, d those without. In Crohn's disease 40% showed history of less than 6 mo. while 60% had less an a yr. history. Whereas no pain was reported ulcerative colitis, 64% of patients with Crohn's sease had pain as a symptom. Diarrhea was common both diseases with bleeding in most of the cerative colitis patients but only 33% of paents with Crohn's disease showed this sign. indolent, painless, irregular ulcer is the pical perianal lesion with fissure and fistula-ano frequently found in Crohn's disease. gmoidoscopy showing irregular separate ulcers with intervening normal or cobblestone mucosa are diagnostic of Crohn's disease. Ba enema shows patchy involvement in the colon in Crohn's disease. Pathological diagnosis of Crohn's colitis rested on tuberculoid granulomata, intramural abscesses, and transmural or serosal inflammation. The presence of the first was a definite indication of Crohn's colitis, though the criterion was used in only 2 cases, the other 31 showed 1 or both of the other diagnostic features. The suggestion is made that a large number of cases of colitis which come to surgery may be examples of Crohn's disease.

10398 IRON ABSORPTION AFTER GASTRECTOMY: AN EXPERIMENTAL STUDY IN THE DOG. (E.) Kelly, K. A. (U. Washington Sch. Med., Seattle), A. Turnbull, E. E. Cammock, C. T. Bombeck, L. M. Nyhus and C. A. Finch. Surgery 62(2):356-360, 1967.

The effect of various gastric operations on the absorption of Fe added to food was studied in mongrel dogs rendered Fe-deficient by phlebotomy. The type of operation and percentage absorption of Fe in each case for 7 groups of animals was as follows: 1) control animals, splenectomy only, 86% absorption; 2) 75-80% distal gastrectomy, gastroduodenostomy and splenectomy, 28% absorption; 3) 75-80% distal gastrectomy, gastrojejunostomy and splenectomy, 22% absorption; 4 and 5) total gastrectomy, esophagoduodenostomy and splenectomy, or gastric bypass with esophagojejunostomy and splenectomy, 2.7-13.0% absorption; 6) 60% proximal gastrectomy and splenectomy, 22% absorption; and 7) total gastrectomy with jejunal pouch interposition and splenectomy, 23% absorption. The effect of ascorbic acid in enhancing absorption of Fe with food was determined in animals with partial gastrectomy and other operations; with a test meal alone, absorption had a mean of 28%, but with admin. of 80 mg ascorbic acid with the test meal, absorption increased to 54%; a further increase of ascorbic acid to 400 mg resulted in a mean absorption of 64%. It is concluded that the presence of the stomach is indispensable for normal Fe absorption.

10399 METABOLIC EFFECTS OF CONTROLLED JEJUNOCOLIC BYPASS. (E.) Shibata, H. R. (Roy. Victoria Hosp., Montreal, Canada), J. R. MacKenzie and R. C. Long. Arch. Surg. (Chicago) 95(3):413-428, 1967.

Observations on the metabolic effects of jejunocolic bypass in 11 grossly obese patients (4 men, 7 women; 20-55 yr. old; wt. range was 193-428 pounds) are presented. The length of jejunum selected for anastomosis was 15 inches (4 patients), 20 inches (5 patients) and 25 inches (2 patients). Wt. loss (which ranged from 67-218 pounds) was noted in all patients and occurred most rapidly in the 15-inch bypass patients; it was directly proportional to the amount of fat excreted in the stool. Diarrhea was a problem in all patients but stabilized within 6-12 mo. after bypass. Xylose studies showed improvement after 6-12 mo. due to prolonged transit time and compensatory increases in absorptive capacity of the jejunum; glucose tolerance curves were flattened as in other series and remained flattened. Glucose i.v. tolerance tests showed 2 frankly diabetic patients maintaining a diabetic pattern postoperatively despite a flattened p.o. glucose tolerance curve. Fat excretion was inversely proportional to length of jejunum used for bypass. Serum cholesterol and total serum lipids were decreased to 40-50% of the preoperative values and remained decreased. Cholesterol esters remained unchanged. Plasma protein levels were decreased immediately after bypass, but became normal with stabilization of wt. Electrolyte difficulties were associated with anorexia, diarrhea, vomitin and nausea. In 1 patient, a low serum Ca level which led to tetany was corrected by raising the serum albumin with the i.v. admin. of normal human serum albumin. Gastric secretion studies were essentially unchanged by the bypass. Pulmonary function improved with wt. loss in all pa tients; 2 patients with alveolar hypoventilation syndrome reverted to a normal ventilation/perfus pattern. Liver function studies which were abnormal immediately after operation all became normal with time; liver structure remained essentially unchanged except in 2 patients. One patient had continuity of the intestine restored for marital and psychological difficulties; 1 death occurred and was attributed to hepatitis. It is concluded that although the jejunocolic bypass is a drastic measure for controlling obesity, it may be justified in a few carefully selected patients.

10400 BILE-SALT DEFICIENCY IN THE STEATORRHE FOLLOWING RESECTION OF THE ILEUM AND PROXIMAL COLON. (E.) Hardison, W. G. M. (Bosto City Hosp., Mass.) and I. H. Rosenberg. New Eng J. Med. 277(7):337-342, 1967.

Four subjects (2 men, 2 women; 45-65 yr. old) with steatorrhea after resection of the lower small intestine were studied; short cholic acid half-lives in all indicated excessive bile-salt loss. A resultant deficiency was manifest in low duodenal bile-salt conc. in 2 of 3 subjects. The same 2 persons incorporated subnormal amount of fatty acid into the micellar phase of the duodenal fluid after a fat meal. In no subject did this bile-salt deficiency substantially inhibit lipolysis of fats, as judged by analysis of lipi classes in the stool. Feeding of sodium taurocholate improved fat absorption in all subjects and increased duodenal bile-salt and micellar fatty acid conc. in the 2 subjects with low valu These findings indicate that, in man, resection the lower small intestine interrupts the enterohepatic circulation of bile salts. The resultan deficiency causes defective intraluminal micelle formation, which is in part responsible for the steatorrhea seen after resection.

10401 JEJUNAL BIOPSY FINDINGS, MUCOSAL DEHYDROGENASE ACTIVITY, AND INTESTINAL ABSORPTION IN PATIENTS WITH COMPLICATIONS AFTER PARTIAL GASTRECTOMIES. (E.) Burhol, P. G. (Ulleval Hosp., Oslo) and J. Myren. Scand. J. Gastroent. 1(4):314-323, 1966.

Mucosal changes in patients with post- (partial) gastrectomy complications were correlated with their dehydrogenase activity, mucosal measuremen and D-xylose and vitamin A absorption. Biopsies

e obtained by Crosby-Kugler's capsule (70-80 cm
m the teeth) in 28 men and women ranging from
76 yr. old, who had undergone (3 mo.-33 yr.
or) partial gastrectomy and gastrojejunostomy.
biopsy, dumping syndrome was present in 15 cases,
patients had lost weight, 3 complained of diar-
a since operation, 2 had ulcers, and 4 had
cinoma of the gastric remnant. Histology and
mistry indicated that some mucosal abnormalities
present in jejunal biopsy specimens from pa-
nts with complications after partial gastrec-
y. Reduced absorptive capacity may be indicated
the decreased dehydrogenase activity and impaired
ylose and vitamin A absorption.

02 EFFECT OF FATTY ACID STRUCTURE ON
ABSORPTION OF FATS BY SPRUE PATIENTS.
) Cancio, M. (U. Puerto Rico Sch. Med., San
n), R. Menéndez Corrada and C. F. Asenjo. Bol.
c. Med. P. Rico 59(4):155-160, 1967.

balance studies were performed initially
a period of 8 days in which a steatorrhea-test
t containing 80-100 g of animal and vegetable
s was given to tropical sprue patients and a
mal control, and continued while substituting
caloricly all of the fat in the diet for 1 of
following sources of triglycerides: 1) medium-
in-triglyceride oil, containing mainly fatty
ds of medium-chain length (20% capric, 78%
rylic); 2) hydrogenated soya oil, containing
nly saturated fatty acids of long-chain length
% palmitic, 90% stearic); and 3) olive oil,
ch contained mainly mono-unsaturated fatty
ds (76% oleic). Each experimental diet was
en for a period of 2 wk. Diet and stool
ples were analyzed for total fat content by
method of Van de Kamer, and for fatty acid
position by gas-liquid chromatography. In
paring the steatorrhea-test and medium-chain-
glyceride diets, all patients had steatorrhea
le on the former; it decreased significantly
le on the latter. Fatty acids present in the
ols of sprue patients were palmitic, stearic
oleic in decreasing order of magnitude. No
ic acid was present in stools of the control
le on the medium-chain-triglyceride diet; ab-
ption of caprylic acid was 100%, and that of
ric was 99% or better. No significant differ-
e in total amount of fecal fat output was
iced while sprue patients were on mono-un-
urated-triglyceride and steatorrhea-test diets;
both cases, fecal fatty acid output consisted
nly of palmitic and stearic acids, with some
ic acid, particularly while on the mono-un-
urated-triglyceride diet; absorption of oleic
d was 95% or more in all cases. In comparison
long-chain-triglyceride and steatorrhea-test
ts, fat output increased significantly while
the former; fatty acid excretion consisted
nly of stearic, and to a lesser degree, palmitic
d. Excretion of oleic acid during the long-
in-triglyceride diet was limited to 0.5% in 1
tient; absorption of stearic acid was poor in
patients. It is concluded that in tropical
rue patients, the longer the chain length of
a saturated fatty acid, the poorer is its absorption; unsaturated fatty acids seemed to be better absorbed than saturated fatty acids, both in sprue patients and in controls. The only fatty acids that appeared to be poorly absorbed by the sprue patients studied were saturated acids with 16 and 18 Ca atoms. Medium-chain triglycerides were absorbed as efficiently by the sprue patients as by the normal controls.

10403 ISOLATED LACTASE DEFICIENCY. CORRELATION OF LABORATORY STUDIES AND CLINICAL DATA. (E.) Welsh, J. D. (U. Oklahoma Med. Ctr., Oklahoma City), V. Rohrer, K. B. Knudsen and F. F. Paustian. Arch. Intern. Med. (Chicago) 120(3): 261-269, 1967.

A total of 170 subjects (109 men, 61 women; 145 white, 22 Negro, 3 American Indians; 3-80 yr. old) without gluten enteropathy had the following studies: 129 had p.o. carbohydrate tolerance tests, 111 had assays of disaccharidase activity on intestinal biopsy specimens, while 70 of the total had both procedures. The patients were divided into 2 groups: 123 with normal lactase activity (including 31 apparently healthy subjects, 24 with partial gastrectomy for peptic ulcer disease, 23 with functional gastrointestinal complaints, 16 with miscellaneous gastrointestinal diseases and 29 with nongastrointestinal conditions) and 47 with an isolated lactase deficiency (including 25 who were otherwise healthy, 7 with stomach surgery for peptic ulcer, 3 each with hepatitis, duodenal ulcers or miscellaneous gastrointestinal diseases, and 6 with miscellaneous nongastrointestinal conditions). Of the normal lactase activity group, 89 had lactose tolerance tests, and all had a max. blood glucose increase of 24 mg/100 ml or more over fasting; 73 had intestinal specimens obtained from the area of the ligament of Treitz, all with lactase activities over 1 U/g wet wt. of mucosa and sucrase; lactase ratios of less than 4:1. Forty of the isolated lactase deficiency group had lactose tolerance tests, and the max. blood glucose increase over fasting ranged from 0-21 mg/100 ml; 38 had intestinal specimens obtained from the area of the ligament of Treitz, all with lactase activities less than 1 U/g wet wt. of mucosa and sucrase to lactase ratios of more than 4:1. Glucose-galactose tolerance tests, the amount of lactosuria during the lactose tolerance test and the levels of sucrase, maltase, palatinase and alkaline phosphatase were similar to those of the normal lactase activity group. The difference in the sucrase to lactase ratio between the isolated lactase deficiency group and the normal lactase activity group was maintained in additional biopsy specimens from other areas of the proximal intestine. There was a higher percentage of individuals with isolated lactase deficiency in the Negroes and American Indians studied than in the whites. Of the normal lactase activity group, 15 gave a history of milk intolerance; in these patients, the milk intolerance was usually associated with intolerance to other foods, it was most common in postgastrectomy patients and rarely produced diarrhea. Fifteen of the 47 patients with an isolated lactase deficiency did not give a history of milk intolerance. All of the remaining 32 subjects gave a history of diarrhea after milk ingestion.

10404 INTESTINAL LACTASE DEFICIENCY AND SACCHARIDE MALABSORPTION DURING ORAL NEOMYCIN ADMINISTRATION. (E.) Paes, I. C. (State U. New York Upstate Med. Ctr., Syracuse), P. Searl, M. W. Rubert and W. W. Faloon. Gastroenterology 53(1):49-58, 1967.

The behavior of lactose absorption during admin. of neomycin or kanamycin (12 g/day) was studied in 10 obese patients using constant (1000 calorie) diets containing 27-155 g of lactose and 4-6-day study periods. Oral lactose tolerance and glucose-galactose tolerance tests were performed during control periods and during admin. of antibiotic(s). The av. increase in blood glucose during the oral lactose tolerance test was significantly less during the admin. of neomycin; a similar but less marked depression of blood glucose elevation was found with the glucose-galactose tolerance test. Lactase activity in the jejunal mucosa was markedly decreased by neomycin ingestion in 4 subjects, and was unaltered when neomycin was added in vitro. Lactose, glucose and galactose were found in the feces by thin-layer chromatography in 9 of 10 subjects given neomycin. Kanamycin did not produce a change in either the lactose tolerance test or the glucose-galactose tolerance test in 1 subject studied, while lactose, galactose and glucose were found in the feces of 2 patients and no saccharide was found in 2 others. In 1 patient undergoing biopsy, the mucosal lactase activity decreased during p.o. admin. of kanamycin. Neomycin was delivered to the proximal ileum by tube in 2 subjects; traces of lactose were found in the feces of both and 1 also had traces of galactose. In 2 patients in whom a formula diet was used to allow the replacement of lactose by glucose, chromatography revealed glucose and galactose in the feces of both subjects during lactose and neomycin admin., but substitution of glucose yielded no sugar in 1 and only faint traces of glucose and galactose in the other. These results demonstrate reversible inhibition of lactase activity and of monosaccharide absorption during admin. of neomycin p.o., and similar, but less marked, effects of kanamycin. This effect of neomycin suggests that widespread mucosal damage contributes to the malabsorption induced by this antibiotic.

10405 MEDIUM CHAIN TRIGLYCERIDES (MCT) IN THE TREATMENT OF PROTEIN-LOSING ENTEROPATHY AND MALABSORPTION SYNDROMES. (E.) Jarnum, S. (State Hosp., Copenhagen) and H. Jensen. Scand. J. Gastroent. 1(4):306-313, 1966.

A total of 18 patients (7 males, 11 females; 6 mo.-58 yr. old) with protein-losing enteropath and other malabsorption syndromes were treated with a low-fat diet supplemented with medium-chain triglycerides. In 4 of 5 cases with prote losing enteropathy, a noticeable improvement of protein loss and steatorrhea occurred; improvement was slight in the fifth patient who had no steatorrhea. In 9 patients with steatorrhea secondary to pancreatic insufficiency (3 cases, including 1 with carcinoma of the pancreas and 2 with chronic pancreatitis), Crohn's disease (of the terminal ileum, 1 case), intestinal resectio (1 case), intestinal resection and blind loop syndrome (1 case), postgastrectomy and enteropat of undefined nature (1 case), sarcoidosis with mesenteric gland involvement (1 case) and genera ized mastocytosis (1 case), clinical improvement followed the institution of a medium-chain-triglyceride diet in every case, whereas steatorrhe ceased in all except 2 patients with chronic pan creatitis. In 4 patients with chronic intestina disease without steatorrhea, the beneficial effect of medium-chain-triglyceride therapy varied A low-fat diet supplemented with medium-chain tr glycerides appears to represent an important advance in the medical management of a variety of malabsorption syndromes.

10406 MALABSORPTION STUDIES IN CIRRHOSIS OF THE LIVER. (E.) Sun, D. C. H. (VA Hosp., Washington, D. C.), R. A. Albacete and J. K. Chen. Arch. Intern. Med. (Chicago) 119(6) 567-572, 1967.

The incidence and cause of malabsorption were studied in 20 patients (all males; 35-69 yr. old with Laennec's cirrhosis; 12 of 20 had severe active cirrhosis of the liver, with clinical sig of jaundice, ascites, and peripheral edema on admission, and histological findings of focal zones zones of necrosis and WBC infiltration. Mallory's bodies were found in 10 of these cases The remaining 8 cases had moderately active port cirrhosis, and in 2 there were features of Zieve syndrome. The presence or absence of steatorrhe was evaluated by fecal fat studies, that of pancreatic insufficiency by pancreozymin-secretin test, and that of small intestine disease by the D-xylose excretion test, X-ray, and p.o. jejunal mucosal biopsies. Chemical steatorrhea was foun in 10 patients; there was no evidence of primary absorption defects of the small intestine, as revealed by D-xylose tolerance test, Ba meal and mucosal biopsy studies. An abnormal pancreozymi secretin test was found in 15 of the 20 patients and in all 10 patients with chemical steatorrhea Replacement with pancreatic extracts produced marked improvement in the fecal fat excretion. These results suggest that pancreatic dysfunctio may have been the primary cause of malabsorption in the 10 patients with Laennec's cirrhosis. All of the patients of this study were alcoholic a population in which pancreatic dysfunction is common. While the interrelationship of cirrhosi and pancreatitis was not investigated, it is pointed out that both cirrhosis and pancreatitis

independently linked to the same cause, e.g.,
holism.

7 IMPAIRED INTESTINAL TRANSPORT OF PROLINE IN A PATIENT WITH FAMILIAL IMINOACIDURIA.

Goodman, S. I. (U. Colorado Med. Ctr.,
er), C. A. McIntyre, Jr. and D. O'Brien. *J.*
at. 71(2):246-249, 1967.

port is presented of diminished intestinal
rption of proline in a severely retarded
-.-old girl with renal iminoaciduria and gly-
ria; at admission, routine urine screening re-
ed prolinuria, hydroxyprolinuria and glycinuria
ne presence of normal serum amino acid levels.
biopsy was normal and there was no chemical
adiological evidence of renal disease. Urinary
rances of amino acids were normal except for
ne, which was 5% of the filtered load; hy-
yproline, which was 66% of the filtered load;
lycine, which was 35% of the filtered load.
parent (father) and 1 sibling showed definite
nuria, and the mother was at borderline
l. The patient and 3 controls were placed
identical diet, rich in gelatin, giving a
daily intake of 10.8 g glycine, 8.6 g proline
ore than 3.0 g of hydroxyproline; examination
e feces after this diet revealed normal ab-
ion of hydroxyproline and diminished absorp-
of proline (59.3 μmoles/24 hr. in feces).
atient is considered to have been heterozy-
for this condition. The results of glycine
ng suggest either increased intestinal ab-
ion, which the fecal amino acid studies did
onfirm (93.4 μmoles/24 hr. in feces after a
gelatin diet), or decreased clearance of
ne from the blood by other tissues, perhaps
ating an even more generally located trans-
defect.

FECAL FAT EXCRETION. AN ANALYSIS OF FOUR YEARS EXPERIENCE. (E.)

Raffen-
er, E. C. (U. Pennsylvania Hosp., Phila-
ia), F. D'Agostino, H. Manfredo, M. Ramirez,
Brooks and F. O'Neill. *Arch. Intern. Med.*
ago) 119(6):573-576, 1967.

esults of fecal fat determination in 149
nts during the 4-yr. period 1962-1966 are
nted; all had ingested standard diets con-
ng 90-100 g of fat/day. More than 90% of
eterminations were done on a 72-hr. or
r stool collection. Abnormality was defined
re than 5 g of fecal fat and more than 200 g
t. of stool. In total, 86 patients had more
5 g of stool fat/day and 69 had more than
wet wt. of stool/day. Of those with ab-
l fecal fat excretion, 23 had pancreatic
nction; there were 19 with chronic pancrea-
, 2 with carcinoma of the pancreas and 2
total pancreatectomy; approx. one-third
ted between 5-10 g of fat/day. Forty percent
ted more than 20 g/day; 2 of the patients
chronic pancreatitis excreted more than 60 g
cal fat/day. Twenty-three of the patients
with elevated fecal fat excretions had small intestinal dysfunction; there were 8 patients with nontropical sprue (adult celiac disease), 1 with tropical sprue, 6 with regional enteritis (Crohn's disease), 6 with varying lengths of small intestine resected and 2 with hypoglobulinemia and small intestinal submucosal infiltration with round cells. Approx. 60% of the nontropical sprue and small-intestine-resected patients excreted more than 20 g of fecal fat/day, while 60% of the patients with regional enteritis excreted less than 15 g of fecal fat/day. There were 12 patients on whom a subtotal gastric resection had been done; 75% excreted less than 15 g of fecal fat/day, and only 2 patients in the group excreted more than 20 g/day. A group of patients with varying diagnoses (malignancies, 3; undiagnosed diarrhea, 9; Fe-deficiency anemia, 3; chronic hepatitis, 2; and 1 each for thyrotoxicosis, rheumatoid arthritis, sympathicotonia, esophageal achalasia, diabetes mellitus, jejunostomy feeding, superior mesenteric artery stenosis, esophageal replacement and gastrostomy feeding; and 3 undiagnosed) excreted fecal fat which ranged as high as 45 g/day. However, more than 50% excreted between 5-10 g/day. The 9 patients with diarrhea of undetermined origin excreted less than 15 g of fecal fat/day. A correlation was found between the wet wt. of stool and the fat content; it was noted that the fecal fat content of the stool could not be predicted by the wt. of the stool and *vice versa*. Another correlation was made between the 24 hr. wet wt. of stool, 24 hr. fecal fat content and the diagnosis; it was found that neither the wet wt. of the stool nor the fat content of the stool demonstrated a definite pattern for diagnosis. In this series, while no definite diagnostic pattern, using fecal fat content and wet wt. of stool, was established, generally a heavy stool with high fat content suggested nontropical sprue or pancreatic dysfunction, while a heavy stool with low fat content suggested regional enteritis.

10409 DELAYED HYPERSENSITIVITY REACTIONS IN THE INTESTINAL TRACT. II. SMALL INTESTINAL LESIONS ASSOCIATED WITH XYLOSE MALABSORPTION. (E.)

Bicks, R. O. (U. Tennessee Coll. Med., Memphis), M. M. Azar and E. W. Rosenberg. *Gastroenterology* 53(3):437-443, 1967.

Twenty-five weaned 13-wk.-old miniature pigs were divided into 4 groups. Animals in Group 1 were skin-sensitized with 3 drops of a 2% alcoholic soln. of 2,4-dinitrochlorobenzene and fed capsules containing 5 g of a mixture of 0.1% 2,4-dinitrochlorobenzene in Orabase 3 times a wk. for 4 mo.; 5 animals in Group 2 were not skin-sensitized, but received identical doses of capsules of 2,4-dinitrochlorobenzene in Orabase. In Group 3, 5 animals were skin-sensitized to the drug, 2,4-dinitrochlorobenzene and fed plain Orabase capsules only, while those of Group 4 were not skin-sensitized and given Orabase capsules only. D-Xylose tests were conducted on the animals, and serial sections of the duodenum, jejunum and ileum were taken for histological examination. A chronic diffuse delayed hypersensitivity reaction was produced by the contactant 2,4-dinitrochlorobenzene, and it was associated with D-xylose malabsorption. The morphological lesion showed severe destruction of the villi with secondary infection in previously skin-sensitized animals. In non-skin-sensitized animals fed 2,4-dinitrochlorobenzene there was edema of the villi with round cell infiltration. Lesions were most severe in the duodenum and decreased in intensity distally. Group 1 animals had the most marked changes, and those in Group 2 were less severe; no gross lesions were noted in animals in Groups 3 and 4. Malabsorption of D-xylose was most marked in Group 1 animals. The immunological nature of the reaction was established by *in vitro* cell migration studies and by the induction of contact dermatitis after intestinal admin. An hypothesis regarding gluten-sensitive enteropathy is proposed as a human model of delayed allergy in the intestine; known gluten-sensitive patients in remission, with normal ileal histology, become acutely ill upon instillation of gluten into the ileum, with clinical symptoms and morphological changes being noted within a few hr. These facts can be interpreted as a delayed hypersensitivity reaction of the contact type occurring in the intestine of gluten-sensitive patients. An experiment in human patients is suggested to verify this hypothesis.

10410 A LIGHT- AND ELECTRON-MICROSCOPIC STUDY OF BACTERIAL INVASION IN WHIPPLE'S DISEASE.

(E.) Dobbins, W. O. III (VA Hosp., Durham, N. C.) and J. M. Ruffin. *Amer. J. Path.* 51(2):225-242, 1967.

Small intestinal biopsy specimens were obtained from a patient with a characteristic clinical history of Whipple's disease, and from 4 additional patients who were either untreated or in relapse, both before and 5-8 wk. after the start of continuous antibiotic therapy; in addition, 7 patients died, prior to the advent of antibiotic therapy, with clinically active Whipple's disease, and biopsy specimens from 4 of these were studied. Specimens were studied by both light and electron microscopy. Bacteria were found to be scattered throughout the lamina propria of intestinal biopsy specimens of the patients with clinically active disease; bacteria were in greatest conc. at villous tips just below the epithelial-cell basal lamina. The most striking finding, and one not previously reported, was the presence of myriads of bacteria within intestinal absorptive cells at villous tips; these bacteria were enclosed within large circular-to-irregular-shaped membrane-bound structures that were best called heterophagic vacuoles, which contained bacteria in varying stages of degeneration, myelin figures, numerous vesicles, glycogen and irregular dense masses. Numerous bacteria were found within macrophages and lymph channels of the single lymph inguinal node obtained from an untreated patient. Bacteria were absent from antibiotic-treated patients in clinical remission, they reappeared with clinical relapse and again disappeared with additional antibiotic
therapy. These previously unreported finding
may explain in part the malabsorption syndrom
seen in patients with Whipple's disease; it i
suggested that passage of chylomicrons throug
the lamina propria may be physically impeded
the sheer numbers of macrophages within the l
propria and by obstruction to lymphatic flow
to prominent involvement of mesenteric nodes.
The lamina propria of the small intestinal mu
appears to be particularly susceptible to bac
of Whipple's disease, and patients with this
ease may be deficient in intestinal plasma ce
Epithelial invasion probably occurs from the
propria, and the route of systemic invasion i
probably through lymphatics draining the inte
The original portal of entry of the bacteria
still unknown.

10411 CLINICAL GIARDIASIS AND INTESTINAL MALABSORPTION.

(E.) Hoskins, L.
(Boston City Hosp., Mass.), S. J. Winawer, S.
Broitman, L. S. Gottlieb and N. Zamcheck.
Gastroenterology 53(2):265-279, 1967.

Intestinal absorptive function and small inte
mucosal morphology were studied in 6 patient
fested with *Giardia lamblia*. Mepacrine effe
eliminated the parasites in all patients in w
it was used. Symptoms subsided spontaneousl
1 patient, and after mepacrine treatment in
tients coincident with elimination of the pa
1 patient died without benefit of mepacrine
apy. Functional evidence of malabsorption wa
found in 4 of 6 patients; it was improved in
mepacrine; malabsorption was more pronounced
carbohydrates than for fats. Diminished ser
levels of thiamine and folic acid in 1 patie
and vitamin B_{12} in another suggested either
cessful competition for dietary sources of t
vitamins by the parasite or their malabsorpt
during infestation. Jejunal disaccharidase
ities were depressed during infestation in 1
tient, and became normal within 10 days afte
mepacrine therapy. Two patients had abnorma
jejunal mucosal morphology of moderate or ma
degree during infestation. Repeat biopsies
1 patient with marked abnormalities returned
idly to normal after mepacrine treatment; th
other 4 patients had milder mucosal abnormal
Electron micrographs in 2 patients showed sh
microvilli. Immunoglobulin deficiency was p
in the 2 patients having the most severe mor
logical and functional abnormalities. These
studies indicate that infestation with *G. la*
produces varying degrees of jejunal mucosal
normalities that are reversed by mepacrine t
ment. These abnormalities, generally mild,
be more severe when associated with immunogl
deficiency. Successful competition by large
bers of *Giardia* for dietary vitamins and nut
essential for intestinal mucosal function ma
an important factor determining the variable
severity of the mucosal lesion.

10412 SMALL INTESTINE IN HOOKWORM DISEAS

(E.) Chuttani, H. K. (Maulana Aza

Coll., New Delhi, India), S. K. Puri and R. C.
a. Gastroenterology 53(3):381-388, 1967.

patients (all men; av. age 27.5 ± 8.6 yr.)
hookworm disease (Ancylostoma duodenale;
duration of symptoms was 9.2 ± 6.8 mo.) were
ed to assess the morphological alterations and
tional derangement caused by this parasite in
small intestine; all of the patients were
c with a hemoglobin of less than 8 g/100 ml.
ols were 25 normal healthy adults and 10 pa-
s with anemia due to bleeding hemorrhoids.
cal manifestations suggestive of malabsorption
infrequent. There was no significant dif-
ce in the mean fecal fat excretion in patients
hookworm disease (4.0 ± 1.3 g), anemia with-
arasite infestation (4.4 ± 0.44 g) and healthy
ols (3.7 ± 1.15 g), although 3 patients with
orm disease had mild or moderate steatorrhea.
ose absorption was abnormal in only 1 patient
hookworm disease. Two-thirds of the patients
hookworm disease or with anemia not due to
itic infestation revealed radiological ab-
lities of the small intestine. One-fourth of
ormal subjects and 50% of the cases of non-
orm anemia had mild (grade 1) jejunal mucosal
malities. Twenty-one of 137 patients with
orm disease had mucosal abnormalities which
grade 1 in 17, grade 2 in 2 and grade 3 in
wo groups of patients were re-investigated,
er eradication of hookworms and the second
correction of anemia without elimination of
. There were no significant changes produced
e function and mucosal appearances of small
tine by eradication of parasitic infestation
rrection of anemia. These findings suggest
hookworms per se appear to produce no major
tinal injury and almost no functional de-
ment.

NEOMYCIN FEEDING IN THE RAT: STUDIES
OF INTESTINAL ABSORPTION OF GLUCOSE
YLOSE. (E.) Broitman, S. A. (Mallory Inst.
, Boston, Mass.), D. Flint and N. Zamcheck.
. Clin. Med. 70(1):9-15, 1967.

male rats (Charles River C.D. strain) were
.91 mM (56 mg%; 58.3 mg/kg/24 hr.) of neomycin
inking water for 4 wk., and the dosage was
ed 3 times at 4-wk. intervals to a max. of
mM (448 mg%; 333.9 mg/kg/24 hr.). No ab-
lities were noted in wt. gain, in xylose ab-
ion, or in morphology of the small intestine.
ls fed 0.91 mM neomycin for 1 yr. showed no
e in glucose absorption during perfusion of
mall intestine when compared to a control
. However, in animals fed only pellets and
, the addition of neomycin to the perfusate
level of 1.2 mM enhanced glucose absorption
-36%. Increasing the conc. to 6.0 mM had no
, while 12.0 mM of neomycin reduced glucose
tion by 12%. It is suggested that the dis-
nt findings of neomycin on absorption are
ed to dosage and the readily reversible ef-
on the mucosal cell surface.

30 CLINICAL COURSE, LATE RESULTS, AND
PATHOLOGICAL NATURE OF INFLAMMATORY
EASE OF THE COLON INITIALLY SPARING THE REC-
. (E.) Korelitz, B. I. (Mt. Sinai Hosp.,
York, N. Y.). Gut 8(3):281-290, 1967.

course of 94 patients (40 men, 54 women)
inflammatory disease of the colon sparing
rectum was analyzed after a mean follow-up
4 yr. (range of 4-36 yr.). The mean age at
t (21 yr., with a range of 8-60 yr.) was
ger than in a comparable series of cases of
rative colitis involving the rectum. The
incidence of internal fistula formation,
rectal suppuration and ulceration, skip areas,
both rectal and colonic strictures supported
oser relationship to regional ileitis than to
rative colitis. Presence of blood in the
l was less common, whereas massive hemorr-
was more common. Complicating arthritis,
tis, nephrolithiasis and erythema nodosum
a higher incidence than in ulcerative
tis, while free perforation occurred less
uently, toxic dilatation rarely and there
no case of colonic carcinoma. Altogether,
were treated without operative intervention,
fly with adrenal steroids; medical therapy
successful in only 16%, although surgical
rvention was postponed for a mean of 3 yr.
he others. Major surgery was performed in
the most common indications were abdominal
or abscess, internal fistulae and colonic
ruction. These patients required a total of
operations, including 165 major procedures,
v. of 3.8 operations/patient. Surgical
ality rate was 14.2%. An ileocolostomy with
ithout resection was done in 66% of the
ents; almost 50% of these later required
stomies, while the remaining 33% had ileo-
ies from the onset. Extension of the disease
ne rectal segment occurred in 15%, un-
oked by surgical intervention, and in 54%
r colonic resection; there was proximal
nsion of the disease to the new terminal
n in 40% after colonic resection. The time
l distal extension varied from mo. to 14 yr.
n, 3 yr.) and with proximal extension, from
to 11 yr. (mean, 4 yr.). At the time of
ow-up, 63% were well, 25% had recurrent
toms or complications, and 12% had died. Of
urgical cases, 47% had ileostomies and 37%
internal anastomoses, including 5 with re-
tomoses. Involvement of the terminal ileum
nflammatory disease of the colon initially
ng the rectum clearly carried a worst
nosis than when the disease was confined to
colon. A diagnosis of granulomatous disease
nade in 72% of the surgical cases; the
nder were considered to be ulcerative
tis. The diagnostic value of clinical and
ological features in determining the patholo-
nature of the disease was evaluated. If
disease was both clinically and radiologically
rative colitis, it proved to be pathologically
lomatous in 65% of the cases; if it was
clinically and radiologically granulomatous, it proved to be granulomatous in 88% of the cases.

10431 DELAYED HYPERSENSITIVITY REACTIONS IN THE INTESTINAL TRACT. I. STUDIES OF 2,4-DINITROCHLOROBENZENE-CAUSED GUINEA PIG AND SWINE COLON LESIONS. (E.) Bicks, R. O. (U. Tennessee Coll. Med., Memphis), M. M. Azar, E. W. Rosenberg, W. G. Dunham and J. Luther. Gastroenterology 53(3):422-436, 1967.

Contactant reactions to 2,4-dinitrochlorobenzene in the guinea pig (Hartley strain, both sexes) was found to be transferred by sensitized cells to a nonsensitized recipient animal; the serum of such sensitized guinea pigs did not transfer the lesion. The reaction was specific for the chemical used (2,4-dinitrochlorobenzene) and did not carry over to a closely related skin sensitizer, trinitrochlorbenzene (picryl chloride). Primary intestinal sensitization was demonstrated in vivo by the development of a positive contact dermatitis after intestinal inj. of the sensitizing conjugate. Sensitization was demonstrated in vitro by inhibition of cell migration with clumping, when cells were exposed to dinitrophenyl conjugates. A similar reaction was produced experimentally in the colon of weaned miniature swine; animals were skin-sensitized to 2,4-dinitrochlorobenzene and this chemical was instilled in an adhesive paste through a colostomy. The lesion produced consisted of mucosal ulceration and hemorrhage, fibrin deposition, edema, small lymphocyte and mononuclear cell infiltration, giant cell formation in the submucosa and vascular congestion with perivascular cuffing. A similar but less intense lesion was produced by prolonged primary contact of 2,4-dinitrochlorobenzene with the mucosa of the colon without prior skin sensitization; skin sensitivity developed in 3 of 4 animals sensitized by direct application of the chemical to their colon. No relationship between circulating antibodies to 2,4-dinitrochlorobenzene and tissue damage was present. Chemical irritation was shown to be unlikely by the use of trinitrochlorbenzene in isolated loops of animals skin-sensitized to 2,4-dinitrochlorobenzene. The inhibition of in vitro cell migration of sensitized cells also confirmed the presence of cellular allergy. Primary intestinal sensitization seems to be dependent upon the ability of the inducer to remain in contact with the mucosal surface. Skin specific protein carriers were found to be unnecessary for inducing the colon lesion. This delayed hypersensitivity colonic reaction is an animal model which may have application to the study of human ulcerative colitis.

10432 IN VIVO MAGNIFICATION ARTERIOGRAPHY OF THE BOWEL WALL. (E.) Bosniak, M. A. (Boston City Hosp., Mass.), L. F. Williams, Jr.,

LIBRARY U. OF I. URBANA-CHAMPAIGN

C. A. Hasiotis, J. J. Byrne and J. H. Shapiro. Amer. J. Surg. 114(3):359-362, 1967.

The technic utilizes photographic magnification arteriography and is based on the principle that radiography giving extremely fine details can be accomplished by use of direct object-film contact. If fine grain (industrial) film and a fractional focal spot X-ray tube are utilized, photographic magnification of 5-10 times the obtained radiograph is possible. Visualization of vessels with an intraluminal diameter as small as 25-50 µ is accomplished. Several examples of visualization in the loop of small intestine of the dog are given; after 60 min. of occlusion of the superior mesenteric vein, marked spasm of vessels and poor filling of smaller branches was seen; after embolization of the mesenteric vessels with microspheres of 50 µ diameter, occlusions of the smaller vessels by the microemboli were demonstrated; and after embolization of the mesenteric vell vessels with microspheres of 150 µ diameter, occlusion of larger vessels was seen, as well as perfusion of contrast media into tiny capillaries in the intestinal wall at points of obstruction. It is thought that use of this technic will lead to a further understanding of various ischemic patterns of the intestines.

10433 VOLVULUS OF THE ASCENDING COLON. A REPORT OF TWENTY-TWO CASES. (E.) Krippaehne, W. W. (U. Oregon Med. Sch., Portland), R. M. Vetto and C. C. Jenkins. Amer. J. Surg. 114(2):323-332, 1967.

Cases (13 women, 9 men; 24-93 yr. old; av. age, 67 yr.) of cecal volvulus in a geriatric hospital population are presented. The diagnosis was primarily derived from patterns determined by radiology. Most commonly, colonic distention appeared to precipitate the volvulus in patients, with an anatomic arrangement conducive to volvulus. History of the patient's illness revealed rectal bleeding in 4, distention in 19, nausea and vomiting in 13, obstipation in 10, constant pain in 9 and colic in 8; physical examination revealed a mass in 4, tender abdomen in 18, obstructive intestinal sounds in 6 and distention in 18. Duration of symptoms ranged from 16 hr.-3 wk. The background for distention evolved into several patterns, including distal obstruction (in 8 patients, the cause of obstruction was due to cancer, diverticulitis, hernia, a tight colostomy and fecal impaction), colonic atony, and swallowed air. The sequence of events leading to volvulus in this series was apparently as follows 1) existence of a mobile cecum; 2) a fixed point around which rotation could occur; 3) distention of the colon; 4) distention of the cecum; and 5) rotation upwards and usually to the left, forming a closed loop in most cases. A history of previous episodes was present in 2 of the patients. In a third of the patients the cecum was folded upward over bands across the ascending colon. Twenty of 22 patients were operated upon; 8 died within 30 days of operat the av. age among these patients who died was 76 yr., and there were no deaths in patients less than 60 yr. of age. Seven of the 8 opera deaths were in patients in whom cecal volvulus developed while they were hospitalized for oth serious illnesses; analysis of the deaths revealed that the condition for which they were hospitalized was the apparent major cause of their death. Cecostomies were performed in 7 patients to relieve distention and fix the cec in 1 case massive gangrene of the abdominal wa followed and was the major contributing factor the death of the patient. In another case, secondary closure was necessary for persistent fecal fistula. Cecopexy was performed in 2 patients; both died without recurrence of the volvulus, the cause of death being due to unrelated disease.

10434 VOLVULUS OF THE CECUM. (E.) Peters H. I. (U. Goteborg, Sweden). Ann. Surg. 166(2):296-299, 1967.

In Göteborg, Sweden (a city with 400,000 inhabitants and only 1 large emergency hospita 11 cases of cecal volvulus (6 men, mean age 57 yr., and 5 women, mean age, 45 yr.) were diagn during the 10-yr. period, 1955-1964. This represented 1% of all cases with intestinal obstructions and 16% of cases with intestinal volvulus. Signs and symptoms were those associated with intestinal strangulation; a fi pre-operative diagnosis was made in 6 of 7 patients submitted to X-ray examination. Ther were 3 cases of gangrenous cecum, and 8 of nor gangrenous cecum. Duration of symptoms was 1- days, and 4 patients had a history of previous abdominal surgery. Treatment was operative ir 10 patients. Of those with gangrenous cecum, had a right hemicolectomy. Of 8 with nongangrenous cecum, 1 each had right hemicolecto detorsion and cecopexy, cecopexy only, detorsi and transverse colostomy, detorsion and cecostomy and laparotomy without cecopexy, while 2 had detorsion only. In 3 cases, spontaneous detorsion occurred during preparation for operation. One patient was moribund upon admission, and no operation could be performed; second died 2 wk. after operation from pulmona embolism. There were no recurrences at follow up 2-11 yr. after operation, including 2 patie in whom only detorsion was done and who were followed for 10 and 11 yr. In cases of nongangrenous cecum, the recommended operation is lateral cecostomy with fixation of the cecum a ascending colon to the lateral abdominal wall

10435 DESMOIDS OF THE ANTERIOR ABDOMINAL WALL IN PATIENTS WITH DIFFUSE POLYPO OF RECTUM AND COLON. (Rus.) Rivkin, V. L. (Proctol. Res. Lab., Moscow) and P. F. Kalite Vop. Onkol. 13(2):38-41, 1967.

Ten of 65 patients operated on for diffuse po posis of the rectum and large intestine

loped desmoid fibromas on the anterior
minal wall; in 8 they appeared after surgery
either malignant polyposis or for cancer on
basis of intestinal familial polyposis
ified in 7 of 10 patients). A 47-yr.-old
developed, 2 yr. after surgery, adeno-
llomatous familial diffuse polyposis of the
um and large intestine with malignant polyps
he sigmoid and transverse colon, a fast grow-
tumor which reached the size of a child's
in 1 yr. Due to pain, chills, and weakness,
. after observation, a resection at the site
luctuation resulted in slight excretion of
A tampon with Vishnevskii's ointment was
ed. However, symptoms of peritonitis
loped on the same day and he died 7 days
r surgery. Autopsy revealed desmoid fibroma.
27-yr.-old woman, 2 yr. after abdomino-anal
ction of the rectum for cancer on the basis
amilial diffuse adenopapillomatous polyposis,
pidly growing desmoid fibroma developed on
abdominal wall in the region of postsurgical
. In the remaining 8 patients a tumor (or
iple tumors in 5 persons) of that location
a benign course. Surgery, X-ray, or chemo-
apy are ineffective in treatment of desmoid
omas. Therefore, desmomas of the abdominal
in patients with diffuse polyposis of the
um and large intestine, represent serious
at times, life-endangering postsurgical
lications. The etiology of desmoid fibroma
nknown and possible causes are discussed.

5 DIVERTICULITIS COLI: A SURGICAL
APPRAISAL. (E.) Asch, M. J. (Columbia
lew York, N. Y.) and A. M. Markowitz.
ery 62(2):239-247, 1967.

nselected series of 209 patients undergoing
ation for diverticulitis coli in a 10-yr.
od is reported; there were 107 women, av.
61.5 yr., and 102 men, av. age 59.7 yr.
e were 116 patients with prior episodes and
no presented for surgery without a history
estive of prior diverticulitis. Signs and
toms included abdominal pain alone in 171
, nausea and vomiting in 13 (6%), abdominal
with palpable mass in 36 (17%), constipation,
8%), diarrhea, 44 (21%), genitourinary,
2%), intestinal obstruction, 24 (11%),
ated WBC and fever, 86 (41%) minor bleeding,
4%) and major bleeding, 23 (11%). Indications
urgery included recurrent attacks in 54
%), perforation in 48 (23.1%), fistula in
bleeding in 23, carcinoma of the colon in 18,
tinal obstruction and abdominal mass in 12
and questionable appendicitis and mis-
neous in 9 and 10, resp. The 2 groups with
most frequent operations were 82 undergoing
oid resection (with or without cecostomy)
4 undergoing the common 3-stage procedure
olostomy, sigmoid resection and colostomy
re. Among the patients, 119 had uncompli-
postoperative courses and 91 patients had
complications, for a complication rate of
. Complications included wound infection
in 27 (12.9%), ileus in 14 (6.7%), pulmonary (significant atelectasis or pneumonia) in 13 (6.2%), urinary tract infection in 11 (5.2%) fecal fistula in 9 (4.3%), cardiovascular (cerebrovascular accident, failure, infarct, arrhythmia) and wound dehiscence in 6 each (2.9%), fever of unknown origin, pelvic abscess, thrombophlebitis and pulmonary embolus in 4 each (2.0%) and others, 39 (18.6%). There was a total of 14 patients who died, for an operative mortality of 6.7%; 7 of the deaths occurred in patients undergoing resections (mortality rate of 3.5%) and 7 occurred in patients who had transverse colostomies only and died during the postoperative period. The av. age at death was 72.6 yr. No death occurred in 55 patients undergoing elective resection for recurrent attacks. The morbidity in this series was considerable, with a 45-day av. patient stay and a 43% complication rate.

10437 SURGICAL MANAGEMENT OF DIVERTICULITIS OF THE COLON. (E.) Wychulis, A. R., O. H. Beahrs and E. S. Judd. Surg. Clin. N. Amer. 47(4):961-969, 1967.

A total of 152 cases (85 men, 67 women; 30-84 yr. old) of diverticulitis treated surgically over the 3-yr. period 1955-1957 are reviewed. The cases were divided into 2 groups: 75 cases of diverticulitis without, and 77 cases of diverticulitis with significant complications. Among 75 without complications, the av. duration of symptoms was 5.3 yr.; among these the symptoms included abdominal pain in 71, abdominal tenderness in 48, fever in 34, abdominal mass in 33 and rectal bleeding in 28. Among those with complications, abdominal pain occurred in 73, abdominal tenderness in 50, fever in 52, abdominal mass in 31 and rectal bleeding in 15. Significant preoperative complications in 77 cases included obstruction in 51, abscess of mesocolon in 47, fistula in 32 and perforation in 2. Ba enema examination revealed diverticulitis in 85, and fistulas were identified in 9 cases. Diverticulitis involved the sigmoid in 136 cases and extended up into the distal portion of the descending colon in many cases; other sites of involvement included the descending colon in 6, the rectosigmoid in 5 and transverse colon in 1. Most indications for surgical treatment were multiple, but chief among them were recurrent diverticulitis in 85, fistula in 32 and single attack of acute diverticulitis in 13. One-stage resection was done in 117 (76%) patients, and an additional 8 (5%) had a resection of the lesion and anastomosis but with a complementary colostomy that required a second operation for closure. Of the 152 patients, 136 were traced for 1-11 yr., the av. being more than 9 yr. The results of surgical treatment were no symptoms in 119 (87%), indeterminate pain in 9 (7%), persisting fistula in 2 (1%), and recurrent diverticulitis which was mild in 1 (1%) and with which required surgery in 5 (4%). Of the 4% who required further surgery for recurrent diverticulitis, the result was satisfactory in all. The overall mortality was 2.6% (4 of 152). During the period of this study, an additional 7 patients (4 men, 3 women; 57-86 yr. old) were seen who had adenocarcinoma of the large intestine coexisting with diverticulitis; in each case, the site of diverticulitis was in the sigmoid and proximal to an obstructing malignant lesion. Operative procedures performed on these 7 included primary resection and anastomosis without colostomy in 3, with cecostomy in 1, and 1 each for abdominoperineal resection, abdominal resection with permanent colostomy and abdominoperineal resection with preservation of the anal sphincters. Three died of metastatic disease 2 mo.-2 yr. postoperatively; 4 had no further symptoms attributable to diverticulitis or carcinoma when last seen at 5, 7, 8 and 9.5 yr. postoperatively, resp.

10438 SOLITARY ULCER OF THE CAECUM. (E.) Maynard, J. (Guy's Hosp., London). Guy Hosp. Rep. 116(1):39-49, 1967.

The relationships of solitary ulcer, solitary diverticulum, benign tumor, and malignancy of the cecum are reviewed from the literature, from the gross and histologic comparison of 2 museum specimens described as solitary diverticula and 2 museum specimens designated as solitary ulcers, all of the cecum, and from the critical evaluation of gross and microscopic material from 4 cases. These cases include 3 men and 1 woman (39-64 yr. old) who underwent right hemicolectomy, 3 for apparent ulcer in a highly inflamed state and the fourth for a supposed carcinoma. Whole histological sections, cut at right angles to the cecal wall, 2 of the apparent ulcers to be inflamed diverticula with complete mucosal lining; in the third the mucosa of the floor of the diverticulum showed evidence of breaking down; and in the fourth, although the mucosa of the lateral walls was intact, the mucosa of the floor was missing. The comparative frequency with which carcinoma of the cecum presents an inflammatory mass makes diagnosis of a benign lesion both difficult and dangerous. In the cecum the likelihood of carcinoma is much higher and rare benign ulcers present emergencies which require surgery; cecal ulcers rarely give rise to symptoms unless they are inflamed or have perforated. Within the limitations imposed by emergency surgery it would seem that an indurated inflammatory mass involving the cecum should be treated by immediate hemicolectomy. Perforation of such a mass should be managed in the same way.

10439 MYENTERIC PLEXUS IN HIRSCHSPRUNG'S DISEASE. (E.) Smith, B. (St. Bartholomew's Hosp., London). Gut 8(3):308-312, 1967.

Sections of colon were obtained by parallel sectioning of the intestinal wall from 2 patients, [1 male, 28 yr. old; 1 female, 26 yr. old] with congenital megacolon. Both specimens of colon measured about 40 cm in length and were obtained from the sigmoid and upper rectum. Sections were taken from the lower end, at 5 cm and 20 from the lower end and from the upper end of t colonic specimens. Histologic examination revealed an almost complete absence of ganglio cells in sections obtained from the lower 2 levels. Ganglion cells were visible at higher levels, however. The normal anatomic pattern the myenteric plexus was lost in lower section Bundles of unmyelinated nerve fibers with an abnormal wavy configuration and large numbers fine, densely packed axons were also observed these lower sections. In sections from higher levels, these bundles were broken up and individual axons were fragmented. Ganglion ce though present in greater numbers at higher levels, were often abnormal in configuration a either showed a pronounced argentophilia or we very pale in color. Some of these cells had n axons or had short branches which were irregul in thickness and randomized in orientation. S neurons were observed among bundles of unmyelinated nerve fibers. Thickened axons were observed following convoluted courses. Some axons entered into the neighboring musculatur and curved back out again, while some had ret tion balls and others showed a great irregula in diameter.

10440 MORTALITY IN NEONATAL HIRSCHSPRUNG'S DISEASE: WITH PARTICULAR REFERENCE ENTEROCOLITIS. (E.) Fraser, G. C. (Hosp. Si Child., London) and C. Berry. J. Pediat. Sur 2(3):205-211, 1967.

Hirschsprung's disease, being congenital, alm invariably shows itself in some way during th neonatal period. In the first mo. of life mortality is in excess of 30%. Postmortem examination of a series of 21 infants with th disease showed that intestinal mucosal change were present. In 4 of 10 patients operated u there developed a sudden circulatory collapse within 48 hr. following successful surgery. 3 more patients who survived surgery there wa gradual decline with wasting, wound breakdown and the development of multiple septic areas- features which have been collectively termed "septic disintegration." Of 7 patients given initial conservative treatment 4 died as a result of mishaps during their early course: 1 infant survived to undergo additional surgery and the remaining 2 children gradually declin as described previously. Preliminary experim data suggests that the pathogenesis of entero colitis resembles that of the localized Schwartzman reaction. Prompt surgery on all newly born infants with Hirschsprung's diseas is required and the bowel should be biopsied only to determine the absence of ganglion cel but to inspect the mucosa as well.

10441 EXPERIENCE WITH THE USE OF INVAGINA SMALL AND LARGE INTESTINE ANASTOMOS AT DIFFERENT LEVELS OF THE LARGE INTESTINE.

;.) Vitebskii, I. D. (Dept. Surg, Kurgan
ional Hosp., USSR). Sovet. Med. 29(12):
51, 1966.

n 1947-1965, 3 variants of the small-large
estine anastomosis were performed on 122
ients with various benign and malignant
eases of the intestines, mesenterial throm-
is and impaction of herniae; the variants
luded 1) terminal invaginating small-large
estine anastomosis; 2) invaginated end-to-
e anastomosis of Kimbarov; and 3) invaginating
nsversal end-to-side anastomosis (the author's
ification) imposed 8-12 cm from the end of
stump of the large intestine. Small and
moid intestine anastomosis in 3 patients was
ording to the side-in-side variant in 1 (1
d), side-in-end in 1 and by the author's
ification in 1. Ileocecal anastomosis in 19
by the side-in-side variant in 11 (5 died),
the Kimbarov technic in 3 (1 died) and by the
hor's modification in 5 (none died). Small
estine anastomoses with the ascending and
atic angle was by the side-in-side variant in
l died). In 96 cases, the small and trans-
sal-colonic intestine anastomosis was by the
e-in-side variant in 57 (11 died), end-in-end
l, by the Kimbarov technic in 16 (2 died) and
the author's modification in 22 (5 died).
-third of the patients with a side anastomosis
d from peritonitis due to faulty sutures; one-
rd who died after the Kimbarov anastomosis
wed faulty sutures, while no one of the pat-
ts who died after anastomosis by the author's
ification showed faulty sutures. The best
g-term results also were obtained using the
hor's modification. Further surgery after side
stomosis was necessary in 4 cases (due to
minal ileitis in 3, or due to syndrome of the
rimal sac with partial intestinal obstruction
l). Therefore, transversal invaginating anas-
osis by the author's modification led to the
mation of a valve arrangement which prevented
erse entrance of the large intestinal content
o the small intestine. In addition, reconstruc-
n of the ileocecal angle function was also rea-
ed by this method. Three case histories (4 mo.,
r. and 64 yr. old, resp.) are given in detail.

42 COMBINED ABDOMINOENDORECTAL RESECTION: REAPPRAISAL OF A PULL-THROUGH PROCEDURE.
) Black, B. M. and J. T. Walls. Surg. Clin.
Amer. 47(4):977-982, 1967.

e (3.2%) of the 157 patients died; 2 from pseu-
embranous ulcerative ileocolitis, 1 each from
ertensive congestive heart failure and pulmonary
olism and 1 from peritonitis ultimately compli-
ed by pulmonary embolism. Complications includ-
l case each of nonfatal pulmonary embolism,
umonia and myocardial infarction. In 2 cases,
arcerated hernia required repair in the immedi-
postoperative period. Dehiscence of the
sion requiring closure occurred in 3 cases
3 developed superficial thrombophlebitis;
abdominal incision became infected in
7 cases. Of 101 surviving men, 26 required transurethral prostatic resection. A minor pelvic abscess developed in 23 patients. Sloughing of the end of the intestine that was pulled through the anorectal canal occurred in 27 cases; in 11 cases (7%), the slough extended to above the level of the stump of the rectum. Of 152 surviving patients, 2 were left with a permanent colonic stoma and in 3 no information concerning fecal control was available. Of the remaining 147, 103 (70%) considered their fecal control to be entirely normal. Some degree of fecal control was present in an additional 25 cases (17%). Essentially no fecal control was regained by 19 patients (13%). It is concluded that combined abdominoendorectal resection is well suited for the treatment of carcinoma of the middle and upper parts of the rectum.

10443 MEASUREMENT OF CONTACT pH IN THE HUMAN RECTUM IN HEALTH AND DISEASE. (E.)
Bitterman, W. (Mayo Grad. Sch. Med., Rochester, Minn.), R. J. Spencer, K. A. Huizenga and R. G. Shorter. Gastroenterology 53(2):288-290, 1967.

Contact pH of the human rectum, measured at the surface of the mucosa, was determined in 7 groups of subjects. In 121 normal subjects (55 men, 66 women; 8.5-83 yr. old), the rectal pH was 7.9±0.067, with no differences found between the results in different decades of age nor between the sexes. Among 17 (6 men, 11 women; 17-78 yr. old) with active chronic ulcerative colitis involving the rectum (the disease had been active 2 wk.-46 yr.), rectal pH was 6.9±0.175; this was significantly different from that of the normals. In 4 patients (3 men, 1 women; 35-68 yr. old) with ulcerative colitis in remission, pH was 7.9±0.150. Of 15 patients (9 men, 6 women; 22-77 yr. old; 2 of whom had nonspecific proctitis) who had diarrhea without ulcerative colitis, the pH was 7.9±0.080. In 29 patients (16 men, 13 women; 35-77 yr. old) with 1 or more benign adenomatous polyps in the rectum, the pH was 8.2±0.070, which was significantly different from that in normals. Fourteen patients (8 men, 6 women; 36-70 yr. old) had previous local resection or fulguration of 1 or more benign rectal polyps; the pH in this group was 8.0±0.006. Of 10 patients (5 men, 5 women; 43-76 yr. old) with rectal carcinoma, pH at the normal rectal mucosa was 7.6±0.260, and at the tumor surface it was 6.9±0.330; both of these were significantly different from normal. Thirteen patients (7 men, 6 women; 45-82 yr. old) had previous resection of rectal or sigmoidal carcinoma, but had no evidence of recurrence; the pH in this group was 8.2±0.100, and this was significantly different from normals. It is speculated that the change to acidity of the pH on the surface of the rectal mucosa in active chronic ulcerative colitis and on the surfaces of the rectal carcinomas probably was a reflection simply of damaged tissue, since tissue damage is associated with a decrease in pH.

10444 CARCINOMA OF COLON AND RECTUM: DIAGNOSIS AND TREATMENT. (E.) Shackelford, R. T. (Johns Hopkins U. Med. Sch., Baltimore, Md.). J. Louisiana Med. Soc. 119(4): 137-146, 1967.

An evaluation of the technic of a synchronous combined abdominoperineal resection of the rectum with preservation of the sphincter is presented. When the best procedure (abdominoperineal exposure with preservation of the anal canal and perineal suture anastomosis of the descending colon to the anal stump) was used in 27 cases it was complicated by a perineal fistula in 9. An operation, evolved from experiments on dogs, for carcinoma of the upper and midrectum employs the 2-team synchronous approach of Lloyd-Davies, the intra-abdominal dissection of Miles combined with the posterior Kraschke approach with sphincter preservation as employed by Best and the pull-through type of coloanal-stump anastomosis used by Block. The operation is described in detail with illustrations. After healing, the patient is discharged from the hospital with a functioning colostomy. After 6-12 wk. when digital examination of rectum, proctoscopy and Ba enema X-ray study have revealed a well-healed anastomosis with a pliable lumen of adequate caliber, the colostomy is closed. This operation has been performed on 15 patients with no operative deaths; 2 died of cancer, one 4 mo. after colostomy closure during which time he had normal anal function. The other had evidence of a rapidly growing cancer so soon after the operation that colostomy closure was not attempted. Another is alive after 1 yr. with recurrent cancer which is being treated by radiotherapy. Except for a fistula in 1, of 12, these have had an uncomplicated postoperative course without evidence of cancer. In all cases sphincter control has been normal. Routine proctoscopic examination of asymptomatic patients over 40 yr. old reveals unsuspected adenomatous polyps or carcinomas in 6%.

10445 VESICOCOLIC FISTULA--A COMPLICATION OF COLONIC CANCER. LONG-TERM RESULTS OF ITS SURGICAL TREATMENT. (E.) Aldrete, J. S. (Mayo Clin., Rochester, Minn.) and W. H. ReMine. Arch. Surg. (Chicago) 94(5):627-637, 1967.

Record analysis of 42 patients (28 men, 14 women) with vesicocolic fistulae is reported. In each patient histopathology had confirmed cancer of the colon and in 38 of them a fistulous communication between the colon and the urinary bladder could be shown by examination of resected surgical specimens. Colonic symptoms occurred in 330/42 while urinary symptoms showed in 40; this was mainly dysuria but 29 showed gross hematuria, 18 pneumaturia and 10 fecaluria. Associated conditions were cardiovascular and renal diseases, polyposis of colon, syphilis, severe diabetes and cancer of the ovary. Urine culture showed Escherichia coli (61%), Streptococcus faecalis (36%) and other gram-negative organisms.
Diagnosis confirmation was through cystoscopy,
proctoscopy and X-ray studies of the colon.
Fistulae were caused by cancer in the sigmoid
colon in 34 patients, in the rectum in 4 and
the cecum in 4. Three of the 42 patients were
operated upon for recurrent malignant colonic
disease and 39 had operations for primary trea
ment of colonic cancer. There were complicati
in 19% involving ventral hernia, pulmonary
embolism, obstruction of the small intestine,
vesico vaginal fistula, fecal fistula, stenos
of uterovesical anastomosis and severe wound
infection; one in each patient. The overall
5-yr. survival rate was 24%.

10446 DIAGNOSIS OF LARGE-BOWEL CANCER IN
ASYMPTOMATIC PATIENT. (E.) Greego
D. H. (Mt. Carmel Hosp., Columbus, Ohio). J.
201(12):943-945, 1967.

In 2000 physical examinations performed in an
internist's office, 7 patients with invasive
carcinoma of the colon were found. None of t
patients in the survey was examined because o
large-intestinal symptoms. All of the 7 pati
had positive tests for occult blood in at lea
1 of 3 stool specimens. This finding led to
preparation of an easier method for multiple
stool examination as a routine office procedu
Recent reports have tended to emphasize the
limitations of the sigmoidoscope in cancer
detection. If a positive reaction is obtaine
from a multiple stool occult blood test, the
patient should be examined further with bariu
sulfate enema roentgenograms. This is one of
the best methods for detecting large-intestin
cancer during routine well-patient examinatio

10447 IMPROVING THE PROGNOSIS FOR PATIENT
WITH INTESTINAL CANCER. (E.)
Gilbertsen, V. A. (U. Minnesota Med. Ctr., Minneapolis). Surg. Gynec. Obstet. 124(6): 1253-1259, 1967.

Cancer of the large intestine is the most com
visceral cancer, and has caused more deaths d
ing the past 25 yr. than any other neoplastic
disease; more than 50% of patients with this
cancer die of the disease. Improvement in pr
gnosis for patients with cancer of the colon
rectum has resulted because of efforts to mak
definitive treatment available for a larger
percentage of patients, greater use of more
adequate operative procedures for patients wi
more extensive cancers, and the treatment of
patients more promptly after onset of the dis
Introduction of the Miles abdominoperineal
resection is one of the most recent significa
improvements in operative procedures for canc
of the rectum. Further improvement in result
has accrued from the use of incandescent
illumination, blood transfusion, improved
anesthesia and other surgical adjuvants. A
gradual increase in the proportion of patient
undergoing excisional procedures is related t

itional improvement in overall survival rates
ing the previous 50 yr. Prognostic improve-
t associated with minimizing of delay in
atment offers the most hopeful area for a
nificant increase in overall rates of survival;
av. patient with intestinal cancer continues
delay at least 6 mo. from the onset of symp-
s until the time of therapy, and lessening of
s delay would appear to have a direct effect
prognostic improvement for a substantial per-
tage of these patients. Even more promising
the effect on survival rates which has resulted
m the detection and treatment of intestinal
cers before such lesions enlarge sufficiently
cause recognizable symptoms of their presence;
the 66% of patients with cancers of the colon
rectum which arise from the distal 25 cm of
estine, annual proctosigmoidoscopy may
minate death from this disease.

48 THE PROGNOSTIC SIGNIFICANCE OF CHROMOSOME ABNORMALITIES IN COLON TUMORS. (E.)
s, H. A. (Yale U. Sch. Med., New Haven, Conn.)
S. Kotler. Ann. Intern. Med. 67(2):328-336,
7.

chromosome complements of 11 primary tumors
metastatic adenocarcinomas, 3 non-metastatic
nocarcinomas, 3 villous adenomas, and 1
enomatous polyp) of the large intestine were
termined. In each of the 10 patients with
lignant or premalignant lesions, chromosome
normalities were present, but the chromosome
plement of a benign adenoma was normal. An
rocentric chromosome, intermediate in size
tween Groups 13-15 and 21-22, was present in
least 3 of the 7 malignant tumors and may
ve represented a significant marker chromosome
adenocarcinomas of the colon. Three subgroups
th distinctive clinical and cytogenetic fea-
res were identified. All of the 4 metastatic
enocarcinomas contained cells with more than
chromosomes; in 3 of these, a predominant cell
ne containing more than 60 chromosomes was
esent. The 3 nonmetastatic colon carcinomas
owed counts ranging only from 44-49, with
edominant cell lines ranging from 46-48. Each
the 3 villous adenomas was characterized both
the absence of marker chromosomes and by the
ck of a predominant cell line. It is suggested
at adenocarcinomas of the colon whose cells
ve high chromosome numbers are more likely to
tastasize than those with chromosome numbers
ose to 46.

449 X-RAY VISUALIZATION OF RECTAL CARCINOMA AFTER INTRAVENOUS INJECTION OF POLY-
NYLPYRROLIDONE (PVP): PRELIMINARY REPORT.
.) Bodkin, L. G. Dis. Colon Rectum 10(3):
7-204, 1967.

ternating inj. of polyvinylpyrrolidone with
and Fe into the arm veins of patients with
ectal carcinoma resulted in visualization of
aque shadows on flat plate X-rays. It is suggested that the deposits observed radiologically are the result of precipitation of Bi by the more active Fe. In patients who received only polyvinylpyrrolidone, the outlines of malignant lesions were distinct, whereas in patients who received other forms of i.v. admin., the borders of the lesions were somewhat indefinite. The lack of toxic reaction to repeated i.v. inj. of polyvinylpyrrolidone was noted. Three cases of rectal carcinoma are described in which this technic was employed. These involved a 58-yr.-old man with advanced carcinoma of the descending colon; a 52-yr.-old woman with carcinoma of the rectosigmoid and a 61-yr.-old man with carcinoma of the rectum and suspected involvement of the sigmoid flexure (confirmed at subsequent abdominoperineal resection). It is suggested that this technic may prove valuable in the early diagnosis of carcinoma of the colon and rectum.

518 FULMINANT ULCERATIVE COLITIS WITH A NORMAL RECTUM. (E.) Sparberg, M. lford Hall USAF Hosp., Lackland AFB, Tex.) and B. Knudsen. Amer. J. Dig. Dis. 12(9):923-933, 7.

erative colitis usually begins in the rectum extends proximally, sometimes eventually olving the entire colon; it can be diagnosed ctoscopically in over 90% of the patients. A mal rectum with severe disease is very ommon, and represents a significant barrier the prompt establishment of a proper diagnosis. r cases of fulminant ulcerative colitis with mal rectal mucosa as observed proctoscopically discussed; all were women, 20-59 yr. old; 3 e Caucasians and 1 Negro; the latter died. case was complicated by toxic megacolon and y hemorrhage. Emergency surgery was necessary 2 cases, with the 1 death resulting; elective gery was performed on 1 patient. Tissue ained in 3 of the 4 cases was typical of erative colitis, with no granulomata, trans-al invasion, deep ulceration, or involvement adjacent lymph nodes. The Ba enema examina-on was the most useful diagnostic tool, even en performed during the acute episode.

519 ULCERATIVE COLITIS CONFINED TO THE RECTUM AND SIGMOID FLEXURE: REPORT OF 4 CASES. (E.) Farmer, R. G. (Cleveland Clin. und., Ohio) and C. H. Brown. Dis. Colon Rectum (3):177-182, 1967.

cerative colitis confined to the rectum and gmoid flexure was studied in 124 patients 8 men, 46 women; age at time of diagnosis nged from 7-75 yr.) who had normal X-rays of e colon. Follow-up information was obtained on 0 patients; 63 were followed for periods nger than 5 yr., the mean period being 6.2 yr. e major symptom was rectal bleeding, which was e primary complaint in 123 patients. Diarrhea curred in 107, 75 of whom had 2-5 loose stools ily, and 32 more than 5 loose stools in a 24-. period. Other symptoms included abdominal amping (rarely severe) in 60, wt. loss of 10 or re pounds in 15 (19 others had lost less than pounds), anal fissures or fistulas in 12, eumatoid arthritis in 2, and uveitis and ythema nodosum in 1 each. The mean duration f symptoms was 3 yr., but the majority of atients (76) had continuous symptoms for less an 6 mo. Sigmoidoscopic findings were ndistinguishable from those of ulcerative olitis affecting more extensive portions of the olon. Biopsy specimens of rectal mucosa of 21 atients were indistinguishable from those of atients with ulcerative colitis. Extension to ore proximal portions of the colon occurred in 0 patients, and the entire colon was involved n 14. Ten patients required operations, of hich 3 were abdominoperineal resections with olostomy; 5 were surgical procedures for toxic ulcerative colitis, and 2 were for carcinoma. No patient required surgical treatment solely for chronic symptoms of colitis. Therapy included sulfa enemas in 28, sulfa agents p.o. in 27, combination of sulfa agent p.o. and sulfa enemas in 20, and steroid enemas and/or steroid suppositories in 18; initial response was satisfactory in 24, 24, 15 and 17, resp., for each group. Antiamoebic therapy was used empirically in 23, with unconvincing results; no amoebae were found in the feces of any of these patients. Among 120 patients studied in follow-up, with regard to initial responses to treatment, 90 had satisfactory responses, 28 had poor responses, and 2 could not be adequately assessed; 33 had no recurrences and 3 reported normal bowel habits without rectal bleeding. Of the remaining 87 patients, 42 had mild recurrences, 28 had numerous recurrences with moderately severe symptoms, including diarrhea and loss of wt., and 17 had severe recurrences, continuous symptoms and significant debility; 7 of these had extremely severe, discrete, toxic episodes of colitis. It is concluded that ulcerative colitis confined to the rectum and sigmoid flexure is more benign and has a better prognosis than colitis involving the entire colon.

10520 ILEOSTOMY AND EXCISION OF THE LARGE INTESTINE FOR ULCERATIVE COLITIS. (E.) Daly, D. W. (Queen Elizabeth Hosp., Birmingham, England) and B. N. Brooke. Lancet 2(7506):62-64, 1967.

From 1947-1965, a total of 442 (180 men, 262 women) patients with ulcerative colitis were submitted to an operative program of ileostomy and total excision of the large intestine; in 149 (33.7%), it was an emergency procedure, and in 293 (66.3%) it was an elective operation. There were 85 deaths, 46 of which were either directly due to operation or within the period of hospital admission. Ten of the deaths occurred after elective surgery, giving a mortality of 3.4%, and occurred in older patients with ages at operation ranging between 42-68 (mean, 54). Mortality in acute cases was 24% (36 deaths after 149 operations). The most common causes of the 39 late deaths were carcinoma (15) and liver failure (7). Only 2 of the late deaths were attributed to surgical treatment and were due to obstruction. Initially, emergency operation predominated over elective surgery, but during the period of this study, this position was reversed. A random group of 100 patients (38 men, 62 women) were reviewed 5 or more yr. after surgery; although the ability to work and enjoy leisure and the state of nutrition was satisfactory in this group, an increased infertility was noted in females, and sexual disability in males. A further 62 men were interviewed, and this finding was corroborated. The cause of sexual disability apparently was technical failure in removal of the rectum. Associated disorders included cirrhosis in 3, diabetes and bronchitis in 2 each, hypertension and chronic nephritis in 1 each, and rheumatoid arthritis presenting in a woman at the age of 68, 5 yr. after panproctocolectomy. It is emphasized that cancer is a serious risk in patients with disease persisting for 10 yr., and it remains a risk if any part of the large intestine is retained.

10521 E. coli AGGLUTINATING ACTIVITY OF ULCERATIVE COLITIS SERA. (E.) Fink, S. (VA Hosp., Hines, Ill.), R. F. Mais, R. F. Locke and A. G. Hall. Proc. Soc. Exp. Biol. Med. 125(2):402-404, 1967.

Antibody titer against "B" antigens was determined in sera from 16 patients with chronic ulcerative colitis and compared with the titer in sera from 17 individuals free of gastrointestinal disease, 23 patients with advanced Laennec's cirrhosis and commercial pooled γ-globulin adjusted to physiologic conc. Eight ulcerative colitis patients were receiving salicylazosulfapyridine, and none were receiving other medication. The pathogenic strain Escherichia coli 0 119:B 14, the equivalent non-pathogenic, non-capsular strain E. coli 0 119 and E. coli 0 14 were used. Control sera agglutinated all E. coli strains tested and gave highest titers against the capsular strain 0 119:B 14; in contrast, sera from patients with ulcerative colitis showed significantly lower agglutinating titers against this organism. An increase in titer did not occur when the low titer ulcerative colitis sera was retested in dilutions of 1:500. Differences due to drug therapy or the severity of the disease were not apparent. A significant difference was not found between normal and ulcerative colitis titers against E. coli 0 119 and 0 14. Sera from patients with cirrhosis showed significantly elevated titers against E. coli 0 119:B 14 and 0 14 when compared to normal values, and similar titers against E. coli 0 119. Commercial pooled γ-globulin adjusted to physiologic conc. gave agglutination titers similar to those of the thermal-inactivated sera from normal subjects with titers of 2+ against E. coli 0 119:B 14 and 1+ against the other strains. These results show that sera from patients with chronic ulcerative colitis have normal agglutinin activity against several 0 antigens of E. coli but decreased activity against 1 capsular antigen; this is due wholly or in part to a decreased content of 19S antibodies.

10522 EFFECT OF E. coli ANTIGENS, TUBERCULIN, AND PHYTOHAEMAGGLUTININ UPON ULCERATIVE COLITIS LYMPHOCYTES. (E.) Stefani, S. (VA Hosp., Hines, Ill.) and S. Fink. Gut 8(3):249-252, 1967.

Peripheral blood lymphocytes of 20 patients with ulcerative colitis and 10 normal patients were cultured in the presence of extracts of Escherichia coli 0 119:B 14, phytohemagglutin and old tuberculin. Following 6 days of incu tion, the degree of blastoid transformation a mitosis was determined by phase contrast micr copy. Lymphocytes from all ulcerative coliti patients studied exhibited a normal reaction phytohemagglutinin and old tuberculin. Howeve those from patients with active ulcerative colitis differed from lymphocytes of patients with the disease in remission and from normal donors in their reaction to E. coli extracts. The observed absent or diminished reaction of lymphocytes from active ulcerative colitis patients was found to be independent of salicylazosulfapyridine therapy and of serum factors. The degree of reactivity varied acco ing to the change in stage of the disease for patients in whom a second study was performed.

10523 PROGNOSIS AFTER SURGICAL TREATMENT O GRANULOMATOUS COLITIS. (E.) Glotze D. J. (Tufts U. Sch. Med., Boston, Mass.), P. Stone and J. F. Patterson. New Eng. J. Med. 277(6):273-279, 1967.

In order to determine the prognosis of granulo atous colitis after surgical treatment, all cases of extirpative surgery for nonspecific inflammation of the colon at the New England Medical Center Hospitals were analyzed. Forty eight patients were considered to have ulcerative colitis, 21 had proved granulomatous coli (these had proven granulomas) and 13 had clini granulomatous colitis (these had typical clini features of granulomatous colitis when granulo were not found in the specimen). The prognosi in granulomatous colitis was not markedly different from that in ulcerative colitis when ileostomy and total colectomy was performed; 4 of 48 patients with ulcerative colitis survive operation and considered themselves well at ti of follow-up, the median of which was 6 yr., with a range of 1-24 yr. Fourteen of 15 patie with proved granulomatous colitis survived operation and were living 1-19 yr. later, with mean follow-up period of 7.5 yr. Recurrent disease was observed, however, in 4 of 7 patients after resection and anastomosis for granulomatous colitis. Dysfunction of the ileostomy was more frequent in patients with granulomatous colitis; these stomal problems occurred solely in ileostomies that had not bee matured at operation. One death resulting from progressive small intestinal disease after colectomy and ileostomy for granulomatous colitis was attributed to this complication. It is concluded that a diagnosis of granulomato colitis should not delay surgical treatment whe medical management fails to control the disease adequately.

10524 SIGNIFICANCE OF LACTASE DEFICIT IN ULCERATIVE COLITIS. (E.) Cady, A. B. (VA Hosp., Hines, Ill.), J. B. Rhodes, A. Littma and R. K. Crane. J. Lab. Clin. Med. 70(2):279-286, 1967.

LIBRARY U. OF I. URBANA-CHAMPAIGN

accharidase assays on biopsies of the small
estine from 32 male patients with ulcerative
itis revealed lactase deficiency in 15 (46%),
ignificantly higher incidence than in control
ients (38 of 122 had lactase deficiency); 30
the ulcerative colitis patients were Caucasian
2 were Negroes. Flat blood sugar curves and
rrhea occurred with 100 g lactose tolerance
ts in the patients with low intestinal lactase
ues; normal curves and no diarrhea were the
al result with normal lactase. All 6 patients
the first yr. of symptoms had a lactase
icit. With repeated biopsies, lactase rose in
atients with clinical improvement and decreased
2 in whom symptoms became worse. In double-
nd feeding trials with 50 or 100 g of sugar
ly in 18 patients, lactose did not increase
ptoms more frequently than glucose. The
urrence of symptoms during the feeding of
ar was not influenced by the presence or
ence of lactase deficit.

25 IMMUNOCHEMICAL AND IMMUNOELECTROPHORETIC
CHARACTERISTICS OF CRYOPROTEIN AND
IOL-GEL TEST IN THE SERA OF PATIENTS WITH
RATIVE COLITIS. (E.) Polčák, J. (Purkyne
Brno, Czechoslovakia), D. Wiedermann, J.
áková and M. Skalova. Gastroenterologia
el) 107(5):273-282, 1967.

g 164 patients with ulcerative colitis, 118
9%) experienced aggravation of symptoms after
sure to cold. The formol-gel reaction
rding to Gaté and Papacostas was positive in
sera of 92 (68.9%) of 134 patients with
rative colitis. Cryoglobulinemia and a
ious history of aggravation of symptoms upon
sure to cold were present simultaneously in
cases. In 14 of the above-mentioned 92 cases,
cryoproteins were studied by the immuno-
trophoresis and immunodiffusion technic of
terlony; the cryoprotein was composed of 2
noelectrophoretic components, namely γ_2 and
immunoglobulins, designated also by sedimenta-
constants 7S and 19S. It is the authors'
ion that cryoglobulinemia in ulcerative
tis is an expression of increased immuniza-
processes in the body.

5 SURGICAL TREATMENT OF NONSPECIFIC
ULCERATIVE RECTOCOLITIS. (Por.)

10536 PROTECTION OF CANINE PANCREATIC ULTRASTRUCTURE AGAINST RADIATION BY PRETREATMENT WITH ALLOXAN. (E.) Volk, B. W. (Jewish Chronic Dis. Hosp., Brooklyn, N. Y.), K. F. Wellmann and S. S. Lazarus. Amer. J. Path. 51(2):207-224, 1967.

In previous studies, the effect of single large doses of X-rays on ultrastructure of the canine pancreas resulted, during the first 3 mo. after irradiation, in widespread focal cytoplasmic degradation characterized by the presence of pleomorphic electron-dense materials, alterations of endoplasmic reticulum and mitochondria, and reduction in size and number of mature zymogen granules; after 3 mo., the lesions gradually disappeared, and after 5 mo., the ultrastructure was normalized. Pancreatic amylase, lipase and leucine aminopeptidase activities were markedly decreased. In order to study the effect of pretreatment with alloxan on these parameters, 48 mongrel dogs of both sexes were divided into 4 groups as follows: Group A: 10 dogs, given partial pancreatectomy followed by irradiation of the remaining 2 inches (approx.) of the uncinate process with 7000-9000 R; Group B, 29 dogs, treated the same as in Group A, except that each also received a single i.v. dose of 15 mg of alloxan monohydrate/kg; it was given to 12 animals at 1-6 days before operation, and to the remaining 17 at 1 hr. before operation; this was followed by a single dose of 7000-9000 R approx. 15 min. after operation; Group C, 6 dogs, first were given 15 mg/kg of alloxan i.v., and 1 hr. later the same operative procedure as in the previous 2 groups was performed, but no radiation treatment was admin.; and Group D, 3 untreated dogs who served as normal controls. The animals in Groups A, B and C were sacrificed at intervals ranging from 30 min.-6 mo. after irradiation or surgery. In the alloxan-pretreated animals of Group B, irradiation-induced extensive ultrastructural alterations of Group A were not observed (aside from occasional minor exceptions); however, a marked reduction in pancreatic lipase, amylase and leucine aminopeptidase occurred similar to those observed in Group A (and described at the beginning of the abstract). In animals of Group C, an equivalent decrease of these enzyme activities was observed in spite of little or no alteration of the ultrastructure. The enzyme decline after admin. of alloxan alone is in keeping with its known reducing effect on protein synthetic activity and the action of this drug on amino groups and -SH radicals. The protection of the fine structure of the exocrine pancreas by alloxan may possibly be explained by the hypothesis that its interaction with amino acids modifies the structure of proteins, particularly those with free amino groups of -SH radicals. No islet changes due to alloxan admin. were observed. Blood sugar values and glucose tolerance curves remained normal in all animals.

10537 SELECTIVE VISCERAL CANINE ANGIOGRAPH FOR PANCREATIC VISUALIZATION. USE O PHARMACODYNAMIC AGENTS. (E.) Lewicki, A. M. (Stanford U. Sch. Med., Palo Alto, Calif.), E. Kupic and S. Kohatsu. Invest. Radiol. 2(2): 119-122, 1967.

Selective and subselective visceral arteriogra (celiac and superior mesenteric arteries) were performed on mongrel dogs (9) after the use of histamine (0.275-0.55 mg), papaverine (15-65 m tolazoline (50 mg), bradykinin (5-100 µg) and trypsin (25-180 mg). Tolazoline produced only minimal vasodilatory changes; the degree of vasodilatation observed after admin. of papave and trypsin was moderate, whereas the most significant changes occurred after use of histamine and bradykinin, the latter being the most effective. The changes observed consiste of a noticeable increase in width of the large vascular branches into which the inj. was made and opacification of a greater number of fine branch vessels at the periphery. All agents produced an enhancement in visualization of th venous phase, the degree of which paralleled t initial arterial vasodilatory effect. A more pronounced degree of opacification of visceral walls and splenic parenchyma was noted in the late phases of the modified angiogram when it was compared to the control study. However, no case could a parenchymal phase be identifie in either the control or the modified angiogra

10538 EVALUATION OF TESTS OF PANCREATIC FUNCTION IN CHRONIC PANCREATIC DISEA (E.) Chey, W. Y. (Temple U. Health Sci. Ctr. Philadelphia, Pa.), H. Shay, O. F. Nielsen an S. H. Lorber. J.A.M.A. 201(6):347-350, 1967.

Pancreatic function tests were studied in 81 patients (67 males, 14 females; 26-83 yr. old with chronic pancreatic disease (65 with chro pancreatitis, 16 with cancer of the pancreas) The tests included pancreozymin-secretin stimulation, fasting serum enzyme levels, sta tolerance, triolein-^{131}I test, and chemical determination of fecal fat. Abnormal results were obtained by analysis of duodenal content in 70 (86%), including 56 with chronic pancreatitis and 14 with cancer of the pancreas; abnormal results were also obtained by serum enzyme (amylase) response in 13 (19%) and by elevated fasting serum enzyme levels in 9%. abnormal serum response was observed more frequently in patients with a mild degree of pancreatic exocrine insufficiency. Abnormal results were obtained by the glucose toleranc test in 56 (69%), the starch tolerance test i 20 (25%) and the triolein-^{131}I test in 29 (36 These abnormal results were observed more frequently in patients with advanced pancreat exocrine insufficiency. Analysis of duodenal contents was the most sensitive and reliable in the diagnosis of chronic pancreatic diseas

9 PANCREATIC ASCITES. (E.) Cameron, J. L. (Johns Hopkins U. Sch. Med., imore, Md.), R. P. Anderson and G. D. Zuidema. . Gynec. Obstet. 125(2):328-332, 1967.

-yr.-old Negro female is reported with normal r function and histologic findings who had tes resulting from chronic pancreatitis; a ew of the literature showed 13 similar cases ascites secondary to benign chronic pan- tic disease, and most of whom had an asso- ed pseudocyst. The patient of this study a history of heavy alcoholic intake during past 12 yr. which amounted to 1 quart of key, 1 quart of wine and 6 bottles of beer wk., most of which was consumed on the wk.-end. his patient, a sphincterotomy was performed, the distal portion of the pancreas, pseudo- and spleen were resected; a Roux-en-Y nal limb was anastomosed to the distal por- of the pancreas. The postoperative course uneventful, the ascites did not recur and patient has remained well. It is suggested pancreatic ascites is a definite clinical ty, currently overlooked because of the ical setting in which it usually occurs: a ent with a heavy ethanol intake. The erentiation of this disorder from hepatic hotic ascites is made on the basis of a ascitic fluid amylase and protein content; protein content of ascitic fluid in hepatic hosis usually ranges between 0.5-1.5 g/100 and the range in patients with pancreatic tes is 2.9-5.7 g/100 ml. In this disorder, ical pancreatic drainage appears to be tive.

0 FURTHER OBSERVATIONS ON TRYPSINOGEN DEFICIENCY DISEASE: REPORT OF A SECOND . (E.) Townes, P. L. (U. Rochester Sch. Dent., N. Y.), M. F. Bryson and G. Miller. ediat. 71(2):220-224, 1967.

irth the infant weighed 2240 g and on dis- ge at 25 days of age he weighed 2211 g; at ime during the 25 days did the body wt. equal xceed the birth wt. On first admission after h, the infant presented with severe hypo- einemia, edema, anemia and growth failure, subsequently developed nutritional hypo- motrichia. The patient responded well to a ein hydrolysate diet supplemented with Fe, anemia and edema persisted for a short time then was corrected within 2 wk. of therapy; wt. doubled within 6-8 wk. of therapy. ound anemia which developed was unresponsive e therapy and persisted in the presence of uate Fe stores; it was rapidly corrected r treatment with Nutramigen (a nutritional ula) and thus was thought to be due to pro- deficiency. There was no trypsin activity spirates of duodenal juice before and after sin activation. The finding of a second unrelated to the first in a single community ests that trypsinogen deficiency disease is ably not a rare disease; 2 cases in 17,588 births (which occurred in Rochester, N.Y. during the 30-mo. period in which the 2 cases of trypsinogen deficiency disease occurred) suggest an incidence of the order of approx. 1 in 10,000. Since this disorder is treatable, it is important to consider it in the differential diagnosis of any infant with hypoproteinemia, edema and failure to thrive.

3 HEMORRHAGIC NECROSIS IN PANCREAS ALLO-
GRAFTS. (E.) Teixeira, E. D. (North-
ern U. Med. Sch., Chicago, Ill.) and J. J.
an. *Arch. Surg.* (*Chicago*) 95(1):79-82, 1967.

l pancreatic allografts were performed in 82
by variations of arterial and venous anasto-
c technic in the presence or absence of
reatic duct ligation as an attempt to eluci-
the pathogenesis of necrotizing pancreatitis.
tal of 52 dogs received a pancreas transplant
g a venous end-to-side technic with a smaller
er receiving transplants with the 2 possible
eties of arterial anastomosis and with or
out duct ligation. Of these 52, 2 trans-
ted glands developed pancreatitis within 24
one was an end-to-end and the other an
to-side anastomosis of the artery. Both had
ted ducts. The remaining 30 dogs were
pients in which the venous anastomoses were
end-to-end. All had ligation of the duct.
his group, there were 26 instances of necrotiz-
pancreatitis. The amylase values of the dogs
h survived more than 18 hr. were higher than
e in the end-to-side anastomosis group. The
splanted glands with pancreatitis showed a
ound vasculitis with perivascular edema,
us wall necrosis, intravascular thrombosis
extravasation of blood into pancreatic
rstitium. Two contributing factors to this
incidence of pancreatitis discussed were
degree of physiologic obstruction which exists
n end-to-end venous anastomosis and the
ificant anatomic arrangement of the left
c vein.

4 SOME PROBLEMS OF EARLY RECOGNITION AND
EVOLUTION OF ACUTE PANCREATITIS. (Rus.)
ova, A. I. (Kalinin Med. Inst., USSR). *Sovet.*
29(12):87-91, 1966.

00 patients (186 females, 14 males; age 21-
than 80 yr.) with acute pancreatitis (de-
ctive form, 6%, acute edema of gland, 94%)
amylase content in saliva (taken on empty
ach or 7 hr. after eating) was increased up
6,384 U. This was shown by modification of
gemuth's method (0.2 ml saliva dissolved in
physiologic soln., then 0.2 ml were diluted
1 ml physiologic soln., and repeated 15
s. A high amylase content in urine (Wohlge-
test) was found in 50% at hospitalization,
9.5% on day 2, and in 43.5% on day 3. De-
se in pain syndrome was accompanied by a
ed decrease in amylase content in saliva,
not in urine. In 37 healthy persons amylase
ent in saliva was 32-64 U. In 100 patients
acute diseases of the abdominal organs,
ase content in saliva and urine was normal
fluctuated between 32-128 U in 99, while in
reached 256 U. A painful spot, at 1.5-2 cm
w xiphoid process in the epigastric region,
acteristic for acute lesion of pancreas, was
d in all 200 patients in an early stage of disease. In passive straighening of the lumbar section of the spine, 73 patients indicated strong pain in epigastric region above the umbilicus. In distinctive forms it occurred early and was persistent despite use of anesthetics. Diet had effects on the course of acute pancreatitis. Elimination of products with high stimulatory activity (white bread, honey, macaroni, meat, and others) assures normal course of the process and prevents early recurrence of the disease.

10565 STUDIES OF EXPERIMENTAL ALCOHOLIC PANCREATITIS IN THE DOG. (E.) Cueto, J. (West Virginia U. Sch. Med., Morgantown), N. Tajen and B. Zimmermann. *Surgery* 62(1):159-166, 1967.

Adult mongrel dogs (35) were divided into 5 groups as follows: Group 1 (20 dogs), in which a Stamm gastrostomy was performed; Group 2, a Roux-en-Y gastrojejunostomy was done; in addition, a gastrojejunostomy was added after a partial pyloroectomy and an end-to-side jejunojejunostomy 10 cm distal to the gastrojejunostomy, and also a Stam gastrostomy; Groups 3 and 4 (5 dogs in each group), a Roux-en-Y gastrojejunostomy and a catheter duodenostomy; and Group 5 (5 dogs), Stam gastrostomy, duodenostomy and cannulation of the main pancreatic duct. Ethanol was admin. 5 times/wk. in a dose of 6 g/kg in animals in Groups 1 and 5, and 1-2 times/wk. in Groups 2, 3 and 4; 95% ethanol was diluted 1:2 using a 0.25 M soln. of $NaHCO_3$ and 500 mg of choline in Groups 1, 2, 4 and 5 (pH approx. 8). In Group 3, 15 ml of 0.1 N HCl (pH approx. 3) was substituted for bicarbonate). Animals were fed a high-protein, high-choline diet. In 5 additional dogs, daily i.v. infusions of equivalent amounts of ethanol diluted 1:3 with sterile 5% dextrose in water were admin. for periods up to 2 wk.; infusion time av. 90 min. Animals receiving ethanol by gastrostomy developed increased blood levels of amylase and lipase, hyperlipemia, hemolysis, inhibition of lipoprotein lipase and histologic changes of chronic interstitial pancreatitis. Peak conc. of serum ethanol occurred during the second hr. after admin. of ethanol; the route of admin. did not seem to alter the rate of absorption. At the end of 24 hr., no ethanol was detected in the serum. Animals in Groups 2, 3 and 4 tolerated ethanol poorly and failed to maintain their normal wt., as opposed to animals in Groups 1 and 5. In the former animals, causes of death were perforated anastomotic ulcers, pneumonia and cardiac failure. These experiments show clearly that ethanol, when given in large doses into the stomach, does produce chronic pancreatitis without liver damage in dogs fed high-protein, high-choline diets. A local neurohumoral mechanism is suggested, since large amounts of acid in the duodenum and/or jejunum are required. Obstruction at the ampullar level did not appear to play an important role.

10566 PEPTIC ULCERATION AND GASTROINTESTINAL BLEEDING IN PANCREATITIS. (E.) Marks, I. N. (Groote Schuur Hosp., Cape Town, South Africa), S. Bank, J. H. Louw and J. Farman. Gut 8(3):253-259, 1967.

The association between peptic ulceration and pancreatitis was examined in a series of 529 patients with pancreatitis, 99 of whom had pancreatic disease unassociated with pain. In 336 patients, alcohol was the major etiological factor, and biliary disease in 80. Pancreatitis due to penetrating peptic ulcers was responsible for 9 cases, and other miscellaneous causes for 59; the etiology was unknown in the remaining 45 patients. Calcification of the pancreas was present in 85 patients. Radiological evidence of peptic ulceration or carcinoma and gastrointestinal hemorrhage was found in 77 (18%) of 430 patients with painful pancreatitis. In fact, however, the incidence of peptic ulceration was only 3.5%. Reasons are suggested for the discrepancy between the incidence of peptic ulceration in this and other reported series. Duodenal cap deformities due to pancreatitis but attributed to peptic ulceration were regarded as a possible cause of this discrepancy, as was the inclusion of a relatively large proportion of patients with clinically unimpressive localized pancreatitis secondary to posterior penetration of a peptic ulcer in any given series. Reference is made to occasional presentation of pancreatitis as an ulcer-type dyspepsia. It is emphasized that the occasional but massive hemorrhage may occur in patients after drainage procedures on a pancreatic cyst, and that a variety of causes are responsible for gastrointestinal hemorrhage in patients during an attack of pancreatitis. The latter include acute gastric erosions or mucosal congestion secondary to contiguous pancreatitis, splenic vein obstruction due to pancreatic compression, the Mallory-Weiss syndrome, alcoholic gastritis and possibly, varices due to cirrhosis. Major causes of hemorrhage in patients who were not suffering an attack of pancreatitis at the time included carcinoma, varices due to cirrhosis and chronic peptic ulceration.

10567 THE ROLE OF GLUCAGON HYPERSECRETION IN THE RELATIONSHIP OF PANCREATITIS AND HYPERPARATHYROIDISM. (E.) Paloyan, E. (U. Chicago, Ill.), D. Paloyan and P. V. Harper. Surgery 62(1): 167-173, 1967.

Ten male mongrel dogs received a constant i.v. infusion of 0.1 kg/kg/hr. of crystalline glucagon in 100 ml of physiologic saline over an 8-hr. period; controls received saline. Following the 8 hr. of glucagon infusion, there was a 2.1 ± 0.2 mg% mean fall in serum Ca, but infusion of saline produced a mean fall of 0.3 ± 0.1 mg%; this difference was highly significant. In a second experiment, nonlethal acute pancreatitis was induced in 6 adult mongrel dogs, while controls underwent laparotomy and manipulation of the duodenum. There was a progressive rise in serum
glucagon to very high levels, attaining a max.
that ranged between 48-120/ng/ml, and in contr
serum glucagon levels fluctuated slightly abov
baseline levels (0-6 ng/ml); serum Ca fell
sharply in both groups, but at 24 and 48 hr.
the experimental dogs attained significantly
lower values than controls. In a third exper
serum immunoassayable glucagon was determined
12 patients with acute pancreatitis and 6 pat
with chronic pancreatitis; a control group of
patients included a variety of intra-abdomina
conditions. There was a marked increase in s
glucagon in most cases of acute and chronic
pancreatitis, in contrast to patients with ot
abdominal complaints. In a fourth experiment
serum Ca and P were determined in 23 patients
with acute pancreatitis, and the same determi
tions were done during the first 4 days of
hospitalization in 15 patients with perforate
ulcers who served as controls. A serum P of
2.5 mg% or less was noted in 18 of 23 patient
with acute pancreatitis, and, in contrast, no
of the patients with perforated ulcers had a
serum P below 2.5 mg%. In the absence of exo
nous Ca admin., there was a temporary rebound
hypercalcemia greater than 10.5 mg% in 8 of 1
of the patients recovering from acute pancrea
Finally, a group of New Zealand white male
rabbits received a daily inj. of 5 mg of crys
line glucagon suspended in a mixture of beesw
and mineral oil, and 8 wk. later their extern
parathyroid glands were excised and examined:
9 of 11 surviving rabbits that received gluca
developed parathyroid hyperplasia, characteri
by a marked increase in cellularity; conspicu
α-cell degranulation was observed in the isle
of Langerhans in all rabbits receiving glucag
It is concluded that there may be an antagoni
between parathyroid hormone and glucagon with
respect to serum Ca, at least in certain situ
tions, and much of the clinical and experimen
evidence suggests that in the syndrome of pan
creatitis associated with hyperparathyroidism
pathologic changes occur first in the pancrea
with subsequent development of parathyroid hy
function.

10568 STUDIES ON THE EXOCRINE PANCREAS.
ULTRASTRUCTURAL INVESTIGATION OF RE
VIRUS PANCREATITIS. (E.) Papadimitriou, J.
(U. Western Australia, Perth) and M. N.-I. Wa
Amer. J. Path. 51(3):387-403, 1967.

A 10^{-2} dilution of hepatoencephalomyelitis vi
the prototype strain of reovirus Type 3 was i
i.p. into neonatal Prince Henry mice, which w
sacrificed, at the rate of 3/day, from the fi
to the ninth days after inoculation; biopsies
the pancreas of these mice were studied by li
and electron microscopy. Pancreases from 9
neonatal mice between the ages of 1 and 9 day
were used as controls. The glandular tissue
the first 3 days after inoculation did not re
any deviations from normal architecture when
compared with specimens from control mice. B
the fourth day, in a few small venules, monoc

e seen containing intracytoplasmic aggregates
virus particles. The lumens of both acini and
tules were dilated, in comparison with normal
trols. From the fifth day, areas of focal
oplasmic degradation or "cytosegresomes" were
dent in the acinocytic cytoplasm, becoming
h more prevalent by the eighth and ninth days
infection; such areas were often large,
suring 5-6 μ in diameter, and were usually
tained within a limiting membrane. In a few
osegresomes, and always within an included
se body aggregates of small, dense structures
suring 250-300 Å in diameter were seen; these
embled nucleoids of Reovirus particles in size
shape. The main pancreatic duct was dilated
there was viral multiplication in the cyto-
sm of cells lining the terminal end of the
creatic duct near its junction with the common
e duct; only those cells lining the main duc-
lumen showed viral replication, and there was
ll no evidence of viral invasion of the cells
ing the smaller lobular ducts by the ninth
of infection, although their lumens were
ated and the lining cells flattened. The
nar lumen remained dilated and often contained
se bodies and myelin figures; many of the
ing cells, in addition to other changes men-
ned, exhibited blebbing of the luminal sur-
e. It is postulated that, although reovirus
invade acinocytes, much of the damage of
virus pancreatitis is the direct result of
truction.

69 IRON ABSORPTION IN CHRONIC PANCREATITIS.
(E.) Balcerzak, S. P. (VA Hosp.,
tsburgh, Pa.), W. W. Peternel and E. W. Heinle.
troenterology 53(2):257-264, 1967.

dies of Fe absorption, Fe stores, Fe kinetics,
er morphology and function, and pancreatic
ction were evaluated in 11 men with chronic
creatitis, all of whom consumed excess alcohol.
secretin test was abnormal in 10, pancreatic
cifications were found in 8, 9 had evidence of
betes mellitus and 7 had steatorrhea. Serum
lase was elevated in 7 of 10 patients, and
um lipase was increased in 2. Some evidence
hepatic abnormality was found in most, if not
, of the 11 patients, but at the time of Fe
orption measurement, significant abnormalities
e detected in only 5. Fe absorption was normal
9 and increased in 2 patients; Fe stores were
rmal or decreased in all except 1 whose increase
slight. The degree of pancreatic insuffi-
ency did not correlate with the quantity of Fe
orbed or in stores. The 2 patients with in-
eased Fe absorption had causes other than
creatic disease to account for the increase;
h were Fe-deficient and had liver disease.
e slight increase in Fe stores seen in 1 patient
have been the result of his mild anemia.
ese findings suggest that increased Fe absorp-
n or Fe stores are unusual in chronic pan-
eatitis, and, when they occur, may result from
other cause. These results indicate that the
creas does not play a significant role in the
trol of Fe absorption.

10570 DUODENAL REFLUX AND THE ETIOLOGY OF PANCREATITIS. (E.) Johnson, R. H. (NIH, Bethesda, Md.) and J. Doppman. *Surgery* 62(3):462-467, 1967.

Three experiments were done on (13) rhesus monkeys (*Macaca mulatta*) of both sexes to investigate the relationship between duodenal reflux and pancreatitis. In the first experiment, 8 monkeys were equipped with a closed duodenal loop by ligation of the intestine at the pylorus and ligament of Treitz. Secretin (20 clinical U) and a mixture of 75 Ivy dog U of cholecystokinin and 300 Crick, Harper and Raper U of pancreozymin was admin. i.v. to each animal 30 and 15 min., resp., before distention of the duodenal loop with Conray 60 to a pressure of 40 cm (of Conray). In 7 of 8 animals, transampullary reflux of contrast material was noted; the time of reflux varied between 1-120 min. after admin. of cholecystokinin-pancreozymin, the av. time being approx. 40 min. All refluxing animals had definite gross and microscopic evidence of varying degrees of pancreatitis, ranging from scattered petechiae and fat necrosis to massive confluent hemorrhage. Serum amylase determinations were done in 4 of 7 refluxing monkeys; in 3 the values were markedly elevated, being 3,100, 2,400 and 8,100 Van Loon U. The monkey that did not reflux was left distended for 2.5 hr.; pancreatitis did not develop, and amylase values did not rise. In the second experiment, 3 monkeys were prepared with closed duodenal loops identical to those of the first experiment; these loops were also distended with Conray 60 to a pressure of 40 cm, which was maintained for 3 hr. No hormones were admin. No gross or histological evidence of pancreatitis was found, and serum amylase values were normal in all instances. In the third experiment, 2 animals were given doses of secretin and cholecystokinin-pancreozymin as in Experiment 1, but no ther manipulations were done; no adverse effects occurred, serum amylase values remained normal and the pancreas was normal. These findings support the hypothesis that duodenal reflux is important in the etiology of human pancreatitis, and suggest a pathophysiological explanation for its occurrence.

10571 ACUTE PANCREATITIS; PATHOGENESIS AND THERAPEUTIC TRIALS. (Kor.) Hong, S. S. (Yonsei Univ. Coll. Med., Seoul, Korea). *Korean J. Intern. Med.* 10(3):149-170, 1967.

Evaluations of the role of alcohol, bile, or other agents on the pathogenesis of acute pancreatitis were made in rabbits and the efficacy of therapeutic agents including Trasylol in the treatment of acute pancreatitis in rabbits and man was studied. Intraductal instillation of bile, ethanol, cholates and HCl resulted in severe parenchymal and fat necrosis of the pancreas. The instillation of trypsin, enterokinase or pancreatic microsome fraction also caused moderately severe parenchymal and fat necrosis. Methanol, myocardial microsomes, saline, or ligation of the pancreatic duct alone caused only edematous pancreatitis. Although the instillation of trypsin brought additional severe hemorrhagic changes, these observations indicate that acute pancreatic necrosis is elicited by the inherent toxicity to the pancreatic acini of the specific agents other than activation of proteolytic enzymes. The severe pancreatitis might be caused by the release of intracellular enzymes or factors resulting from an admixture of pancreatic juice and bile or alcohol. The max. rise in both serum amylase and lipase occurred on the first postoperative day; serum lipase returned to preoperative levels on the third day, and serum amylase on the fourth day. The levels of both serum enzymes were paralleled with the severity of pancreatitis. The survival rate of animals with bile-induced necrotizing pancreatitis was significantly increased in a decreasing order in groups treated with Trasylol, hexamethonium and acetazolamide. Atropine and propylthiouracil were also effective but cortisone did not change the mortality rate. In the animals treated with drugs the development of parenchymal necrosis appeared to be delayed. Particularly, Trasylol-treated animals had less hemorrhagic or fatty necrosis. Clinically, Trasylol brought a faster recovery in 10 patients with acute pancreatitis and no mortality was observed in this group. Trasylol tended to decrease the frequent use of opiates and in some patients caused a dramatic relief of pain.

10586 SPLANCHNICECTOMY IN THE TREATMENT OF CHRONIC PANCREATITIS. (It.) Prior, C. (U. Genoa, Italy), P. P. Paoletti and S. Troncone. Minerva Chir. 22(14):809-814, 1967.

87 EFFECT OF BILE AND BILE ACIDS ON THE
ACTIVITY OF CHOLINESTERASE. (Rus.)
tovit, V. A. (Kiev Infect. Dis. Sci. Res.
t., USSR) and E. P. Tkachuk. Vrach. Delo
:116-118, 1967.

dy with albino mice (20 g wt.; total 300),
s (230-300 g wt.; total 27) and rabbits (2100-
0 g wt.; total 43) showed that bile and bile
ds during prolonged i.v. and p.o. admin. de-
ased cholinesterase activity in the blood as
pared to controls. In mice inj. i.v. with bile
1 ml (0.5 mg)/day x 10] serum cholinesterase
ivity decreased by 14.2% and hepatic and cardiac
ivity of the enzyme increased by 12.22 and
32%, resp. Cholic acid (160 mg/day x 14, p.o.)
sed in rats a decrease of blood cholinesterase
ivity by 51.77%, and an increase of that in
er and heart by 26.35 and 21.62%, resp. In
bits serum cholinesterase activity decreased
er 6 days of i.v. treatment [dose 0.5 ml/kg/day
mg/kg/day) for 12 days; bile was given also
18 days] with bile by 20.82%, with deoxycholic
d by 67.52%, with cholic acid by 36.54%, and
h lithocholic acid by 69.66%. After 12 days of
atment cholinesterase activity in serum con-
ued to decrease only after bile, here it showed
e increase but did not reach its initial level.
er 12 days of treatment the cholinesterase
ivity in liver and heart tissue increased with
e by 48.66 and 50.77%, resp.; with deoxycholic
d by 68.98 and 81.44%, resp.; with cholic acid
80.14 and 135.49%, resp.; with lithocholic acid
56.5% and uncertain increase, resp. Therefore,
is assumed that the decrease of serum cholin-
erase activity in the patients with obstructive
ndice, accompanied by prolonged cholemia, de-
ds on lesions of the hepatic parenchyma, which
urred as a result of the toxic action of bile
bile acids.

88 COCHLEAR FUNCTION IN PATIENTS WITH
DISEASES OF THE LIVER. (Rus.)
'shmein, L. I. (Avitsenny Med. Inst., Tadzhik-
an, USSR). Vestn. Otorinolaring. 29(4):50-55,
7.

aring acuity (tonal and speech audiometry) was
died in 110 patients (64 males, 46 females;
mostly up to 40 yr.) with acute infectious
atitis, and in 51 with chronic hepatitis and
with liver cirrhosis (103 of 157 are males over
yr. old). In the acute infectious hepatitis
ses, decreased hearing at frequencies of 4096
8192 hertz was found in 31 (with moderate-
vere form), 19 of these were bilateral and 12
ilateral. Following treatment hearing was
rmal in 19 and unchanged in 12. Complete deaf-
ss following acute infectious hepatitis oc-
rred in one 5-yr.-old. In decreased hearing was
und in 91 (58%) of the patients with chronic
patitis and cirrhosis. Otoscopy showed depressed
mpanic membrane in 21 (13%) and chronic
suppurative mesotympanitis in 4. Four types of audiograms were determined in the group of chronic hepatitis and cirrhosis patients. Type 1 (significant decrease of perception in the region of low frequency and slight in the region of high frequency) was found in 16 (10%) patients with moderately drawn-in tympanic membrane; Type 2 (marked decrease of hearing at frequency 4096 and 8192 hertz with slight decrease at 2048 hertz and almost normal level at other frequencies) in 34 (21%) patients. Type 3 (hearing decrease at all frequencies, greater at high) was found in 38 (36%) with liver cirrhosis; Type 4 (decreased hearing at all frequencies in 1 ear and decreased hearing only at frequency 4096 hertz in the other ear) occurred relatively seldom (4%) in patients with liver cirrhosis. Therefore, exacerbation in the course of this process in the liver is accompanied, as a rule, also with exacerbation of cochlear function. Two case histories are given in detail.

10589 CHANGES IN THE PROTHROMBIN COMPLEX COMPONENTS (PROTHROMBIN,PROCONVERTIN, PROACCELERIN) IN CHRONIC HEPATITIS AND CIRRHOSIS. (Rum.) Stanescu, M. (Cantacuzino Hosp., Bucharest) and F. Stroescu. Med. Intern. (Bucur.) 19(4): 417-423, 1967.

In 12 patients with chronic hepatitis Quick time was 14-20 sec., prothrombin time (Factor II) was 35-70 sec., proaccelerin time (Factor V) was 20-30 sec. and proconvertin time (Factor VII) + Factor II varied between 51 and more than 90 sec. Determinations of the same components in 33 cases of cirrhosis revealed that Quick time was 15-23 sec., Factor II was 35-85 sec., Factor V was 20-40 sec. and Factor II + Factor VII varied from 60 to more than 120 sec. In 20 controls, Quick time was 13-16 sec., Factor II was 30-50 sec., Factor V was 18-30 sec., and Factor II + Factor VII varied between 40 and 51 sec. The results indicate that components of the prothrombin complex are consistently altered in both chronic hepatitis and cirrhosis, with the latter showing more significant alterations. Prothrombin and proconvertin underwent the most drastic modifications which may be due to the fact that both of these factors are synthesized mostly, if not exclusively, in the liver.

10590 THIAMINE AND ITS PHOSPHORYLATED ESTERS IN HEPATIC DISEASE (NOTE III). (Rum.) Manta, I. (Sch. Chem. Biol., Cluj,,Rumania), V. Gorun and N. Hîncu. Fiziol. Norm. Pat. 12(6): 531-534, 1966.

Thiamine and its esters (thiaminemonophosphate, thiaminepyrophosphate, and thiaminetriphosphate) were lower in the serum of 53 patients with various pathological liver conditions than in controls (thiamine - 5.2, thiaminemonophosphate - 6.8, thiaminepyrophosphate - 8.5, thiaminetriphosphate - 6.1 mg % serum). The smaller variations were noted in cases of cirrhosis (6 of 53; thiamine - 3.10, thiaminemonophosphate - 4.46, thiaminepyrophosphate - 3.28, and thiaminetriphosphate - 1.7 mg% serum) and in active chronic hepatitis (23 of 53; thiamine - 3.05, thiaminemonophosphate - 2.97, thiaminepyrophosphate - 2.54, and thiaminetriphosphate - 2.40 mg% serum). The lower values were obtained in cases of hepatitis with associated heart disease (thiamine - 0.02, thiaminemonophosphate - 0.09, thiaminepyrophosphate - 0.06, thiaminetriphosphate - 0.30 mg% serum. In 6 cases of toxic hepatitis (caused by intoxication with benzene, or polyvinyl chloride, or Hg) the values return to normal upon improvement of the patient's condition. The study of the relationship between the phosphorylated thiamine esters in patients with cirrhosis and active chronic hepatitis reveals increase of thiaminemonophosphate as compared to significant decrease of thiaminepyrophosphate, indicating that although thiamine is normal, the transformation of thiamine into carboxylase is not stoichiometric. In liver hepatitis associated with heart disease the conc. of thiamine and its esters, while low, are not greatly different, while in toxic hepatitis the values vary according to the case and are not characteristic. Pyruvic acid was higher in the serum of patients studied than in controls, the greater values being obtained in cases of hepatitis and associated heart disease (where cocarboxylase had its lower values) while liver cirrhosis patients had the lowest values. The values of ATP were proportional to pyruvic acid and inversely proportional to cocarboxylase.

10591 METHOD FOR STUDY OF EXTERNAL SECRETION OF LIVER IN DOGS WITH INTACT GALLBLADDER AND HEPATO-INTESTINAL CIRCULATION. (Rus.)

Nesterin, M. F. (Inst. Nutr., Acad. Med. Sci., Moscow) and R. V. Narodetskaia. Biull. Eksp. Biol. Med. 63(5):121-122, 1967.

A method is described that preserves the entire cholagogic system with exclusion of a duct from 1 of the hepatic lobes in which a canula is induced. The duct of the left liver lobe was ligated, at the site of its inflow into the common bile duct, by a thread and the latter was placed under the free part of the duct between the hepatic lobe and established ligature; then the duct chosen for cannulation was partially incised, and the cannula induced into the first sleeve tubule and was fastened in the duct by the supplied thread; with another ligature the tubule was fixed to the duct from the other side of the sleeve, the tubule was fastened on 2 sides of the following sleeve to the external surfacr of duodenum in the region of inflow of the common bile duct. Some supply of the tubule was left in the abdominal cavity while its remaining part was fixed to the internal surface of abdominal cavity in both sides of the sleeves; the tubule end (6-8 cm long) is left as an outlet in the wound. Several days after surgery in dogs the conc. of bile components, excreted on an empty stomach before food stimulation, was at lower levels. Combination of this method
with the method earlier reported enables deter
mination of conc. ability of gallbladder under
natural conditions, and total amount of bile e
creted by liver with a normally functioning ga
bladder. The disadvantage of this method is
partial loss of bile. Cannulation of the hepa
lobe was made on rats which enabled exclusion
total bile loss from the process of digestion.

10592 EXPERIMENTAL AUTOIMMUNE HEPATITIS.

Morettini, A. (U. Florence, Italy),
A. Corradi, F. Pacini, A. Ghetti and G. Berni.
Folia Allerg. (Roma) 13(6):407-421, 1966.

The possibility of inducing experimental autoi
mune hepatitis by various technics was studied
120 Sprague-Dawley rats (wt. 150-200 g). In
Experiment 1, rats were treated s.c. with auto
ogous whole liver extracts (0.5 ml) in Freund'
adjuvant (0.5 ml) once a wk. for 10 wk.; histo
examination in these animals revealed parvicel
infiltration of the portal spaces as well as d
generation and piecemeal necrosis of single or
groups of hepatocytes; controls treated with a
ogous whole liver extracts alone or with Freun
adjuvant alone showed no hepatic changes; hepa
alterations were prevented in rats treated wit
autologous liver extracts and Freund's adjuvan
with the admin. of hydrocortisone hemisuccinat
(2.5 mg/day s.c. for 10 wk.) or triethyleneimi
benzoquinone (2.5 µg i.p. twice a wk. for 10 w
In Experiment 2, rats were treated with homolo
microsome liver fractions (0.5 ml/wk.) and Fre
adjuvant (0.5 ml/wk.) for 10 wk. or with homol
ribosome liver fractions (0.5 ml/wk.) and Freu
adjuvant (0.5 ml/wk.) for 10 wk.; no significa
hepatic changes were observed at histological
examination in these animals. Nor were any ch
observed in rats treated with homologous micro
or ribosome liver fractions without Freund's a
juvant. In Experiment 3, rats subjected to
splenectomy after 5 wk. of treatment with auto
gous whole liver extracts (0.5 ml/wk. s.c.) an
Freund's adjuvant (0.5 ml/wk.) showed a worsen
of the hepatic alterations observed in Experim
1: distortion of hepatic lamina, perilobular a
focal necrosis, and marked lymphocyte infiltra
of portal spaces. No changes were observed in
animals subjected to splenectomy 10 days prior
the beginning of treatment.

10593 THE LIVER IN THYROTOXICOSIS. (E.)

Dooner, H. P. (U. Chile, Santiago),
J. Parada, C. Aliaga and C. Hoyl. Arch. Intern
Med. (Chicago) 120(1):25-32, 1967.

Biochemical and histological studies of the liv
of 15 patients with hyperthyroidism and 8 thyro
patients without thyrotoxicosis showed no paral
lelism between the liver function tests and the
biopsy findings in either group. However, the
liver function tests were deranged in the major
of the patients with thyrotoxicosis. The cepha
cholesterol flocculation reaction, the thymol t
bidity test, the serum alkaline phosphatase val

the plasma prothrombin time were all abnormal his group. The changes seen in the biopsy imens of this same group were: cytoplasmic ification in 8 cases, cytoplasmic vacuoliza- in 5 cases, absence of nuclei in 6 cases, ation in nuclear size in 5 cases and hyper- matism in 6. Other pathological changes were tosis in 3 cases, round cell infiltration in moderate increase of portal connective tis- in 5 and engorgement of the central vein in 4. omparison, in the second group of 8 patients flocculation tests were significantly changed nly 2 cases and histological changes were ificant in only 1 case. Cytoplasmatic clari- tion was notable in 2 cases. Steatosis was ent in 2 cases. The discrepancy in the fre- cy and severity of liver injury in this re- as compared with previous ones is explained he fact that the changes in the hepatic cell liver function are reversible.

4 GLUCOCORTICOIDS IN COMBINED TREATMENT OF CHRONIC LIVER DISEASE. (Rus.) dar, Z. A. Ter. Arkh. 39(3):13-20, 1967.

atment with glucocorticoids (prednisolone; -2215 mg in 2 wk. - several mo.) in 100 pa- nts (hepatitis, 25, cirrhosis, 75) had a favor- e effect on appetite and general conditions decreased both serum bilirubin level and trans- nase activity; however, they had no effect on functional condition of the liver. In Group 1 tive chronic hepatitis and liver cirrhosis), of patients with active chronic hepatitis, predni- one (40 mg/day gradually decreased, up to 12 duration) was effective in 10; of 46 patients h liver cirrhosis (postnecrotic, 26, portal, 20) exacerbation, prednisolone (20-25 mg/day dually decreasing, to 2 mo.) induced marked jective improvement while tests showed positive fts in 17, slight improvement in 15, and none 14. In Group 2 (cholestatic hepatitis and iary liver cirrhosis) all 7 patients with ndice were cured by prednisolone (30-40 mg dually decreasing, 2-3 wk.); good immediate ect occurred in 4, while none occurred in 3 of atients treated for cholestatic chronic hepa- is. Of 5 patients with biliary cirrhosis, dnisolone (20-25 mg gradually decreasing, dura- n to 2 mo.) caused improvement in 2 and slight 3. In Group 3 (liver cirrhosis with ascites) treatment with prednisolone (15-20 mg gradually reasing 2-3 wk. and combined with diuretics) ites disappeared in 6, decreased in 9, remained hanged in 7 and increased in 2 of 24 patients. le effects include gastric hemorrhage in 2 and olonged occurrence of blood in feces in 5. Data some symptoms following treatment with (over patients) or without (50 with chronic oatitis and liver cirrhosis) prednisolone e compared. In groups treated with predni- lone or in those not treated, a decrease in akness was found in 77 of 86 or 38 of 44, sp., of reduced appetite in 30 of 82 or 8 of , resp., of jaundice in 41 of 54 or 15 of 24, sp., of diuresis in 4 of 65 or 3 of 40, resp., of ascites in 22 of 30 or 3 of 8, resp., of leukopenia in 30 of 68 or 11 of 21, resp., and of thrombocytopenia in 15 of 40 or 4 of 18, resp. Alanine transaminase activity decreased in 42 of 53 following therapy with prednisolone. Two case histories are given in detail.

10595 BLOODLESS REMOVAL OF THE LIVER LOBES AND SEGMENTS WITH COMPRESSION OF HEPATODUODENAL LIGAMENT. (Rus.) Orlova, L. P. (5th Clin. Hosp., Minsk, USSR). Eksp. Khir. Anest. 12(2):39-42, 1967.

Surgery was performed on 16 random-bred dogs, age 2-5 yr. The abdominal cavity was opened, the hepatoduodenal ligament containing the portal vein, hepatic ducts and artery were isolated, and the latter pressed by vascular clamp for 15-60 min. One of the lobes or a necessary segment of the liver was freed and vessels of the removed part were isolated transparenchymatously; 1-1.5 cm below the segmentary vessels, the liver capsule was dissected, liver parenchyma was divided and vessels approached. Vascular clamps were placed on isolated vessels of the removed segment or hepatic lobe, marked parts of liver were resected, vessels were ligated by silk, and the hepatic wound remained bloodless during the entire period. After removal of the clamp the abdominal cavity was closed without drainage. Of 8 dogs operated on under conditions of hypothermia, 6 endured surgery, while of 8 dogs operated on under general ether-O_2 narcosis only 1 survived. Pathological-anatomical study of the dogs which died showed hepatic hemorrhages, polyemia, edema of hepatic canaliculus and lungs, and extensive hemorrhages in the gastrointestinal tract. Upon pressing of hepatoduodenal ligament 3 types of hepatic injuries were found (bile stasis, stasis in the portal vein, hepatic exsanguination). Around days 5-6 survivors were cheerful, ate well and shifts in liver function were absent; therefore, such a pressing dried the organ and enabled bloodless removal of parts of its parenchyma. Hypothermia increased time of liver ischemia. The best time for pressing ligature was 15 min.; and under conditions of hypothermia, up to 30 min.

10596 PORTAL VEIN THROMBOSES IN MALIGNANT HEPATOMA. (E.) Albacete, R. A. (VA Hosp., Washington, D. C.), M. J. Matthews and N. Saini. Ann. Intern. Med. 67(2):337-348, 1967.

A total of 25 cases (all males; 33-76 yr. old, av. age 58; 15 Negro, 8 Caucasian and 2 Oriental) of primary liver cell carcinoma were studied, and 100 cases each of cirrhosis and metastatic carcinoma to the liver were reviewed, to determine the prevalence of portal vein thromboses. The value of splenoportography as a useful adjunct in diagnosis of hepatoma was also assessed. The 25 cases of hepatoma were subdivided into clinical types; 10 were of Type 1, representing patients with known cirrhosis and a rapid downhill course; 9 were Type II, patients with unexplained hepatic insufficiency; 3 were of Type III, metastatic disease or other organ pathology; and 3 were Type IV, those with a picture of biliary obstruction. Abdominal pain was a significant complaint in only 7 (28%), and the outstanding feature was palpable enlargement of the liver; ascites was found in 16 (72%), and liver function tests showed mild hepatic dysfunction in 8 (32%) cases; the remaining 17 showed gradual elevation of bilirubin and SGOT. Scintillation scanning of the liver was performed in 5 cases and demonstrated space-occupying lesions in 4 cases. At autopsy, 18 of 25 hepatomas were associated with a coarsely nodular or postnecrotic variety of cirrhosis, 3 with nonspecific portal fibrosis, 2 with a mixed Laennec and postnecrotic pattern and 1 each with Laennec's cirrhosis and hemochromatosis with pigment cirrhosis. Liver wt. ranged from 900-7500 g, with an av. of 2780 g. In 8 cases (32%), there were grossly demonstrable thromboses of the extrahepatic portal venous system. Of these 8, 4 had massive tumors predominantly involving the right lobe, and the remaining 4 patients had multinodular tumors; in all of them, tumors were poorly differentiated, had metastasized to other organs and were associated with some degree of ascites. Of 100 cases of cirrhosis, most of whom were chronic alcoholics; bland portal vein thrombi were identified in 5. Of the 100 patients with carcinoma metastatic to the liver, portal vein thrombi were found in 5. Thus, portal vein thrombosis was found 6 times more frequently in patients with malignant hepatomas. The limitations of splenoportography in the diagnosis of portal vein thrombosis, as well as its value in diagnosis of hepatoma, are discussed; splenoportography is particularly contraindicated in patients with coagulation defects or in the presence of marked ascites. The diagnostic value of determining the presence of an extrahepatic portal vein thrombosis in hepatoma is stressed.

10597 SYSTOLIC LIVER MURMURS IN PRIMARY CARCINOMA OF THE LIVER. (E.) Zuidema, P. J. (Free U., Amsterdam, Netherlands) and C. Van Der Meer. Trop. Geogr. Med. 18(4):265-271, 1966.

Auscultation of a soft, systolic murmur over the liver of patients with primary liver carcinoma was studied in 20 patients in Indonesia with malignant hepatoma. Sounds were heard over the tumor in more than 50% of the cases, and were classified as hepatic friction rub, para-xiphoid-umbilical hum, and systolic murmur. Case histories given were of a 25-yr.-old farmer and a 25-yr.-old Japanese woman. Three cases were also given of patients from Amsterdam: a 59-yr.-old man, a 57-yr.-old man, and a 56-yr.-old woman. It is supposed that the murmur is associated with the pathological vascularization of the tumor, and the sound is considered to be a diagnostic sign.

10598 DIFFERENCE IN HEPATIC METABOLISM OF
LONG- AND MEDIUM-CHAIN FATTY ACIDS:
THE ROLE OF FATTY ACID CHAIN LENGTH IN THE PRO
DUCTION OF THE ALCOHOLIC FATTY LIVER. (E.)
Lieber, C. S. (Bellevue Hosp., New York, N. Y.
A. Lefèvre, N. Spritz, L. Feinman and L. M.
DeCarli. J. Clin. Invest. 46(9):1451-1460, 19

Replacement of dietary triglycerides containi
long-chain fatty acids by triglycerides contai
medium-chain fatty acids markedly reduced the
capacity of ethanol to produce fatty liver in
After 24 days of ethanol and medium-chain fatt
acids, the increase in hepatic triglycerides
only 3-fold that of controls, whereas an 8-fol
elevation was noted after ethanol and long-cha
fatty acids. The triglyceride fatty acids tha
accumulated in the liver after feeding of etha
with medium-chain fatty acids contained only
small percentage of the medium-chain fatty aci
their composition also differed strikingly fro
that of adipose lipids. In order to study the
mechanism of the reduction in steatosis, oxida
to CO_2 and incorporation into esterified lipi
of ^{14}C-labeled chylomicrons or palmitate-^{14}C
(representing long-chain fatty acids), and of
octanoate-^{14}C (as medium-chain fatty acids) we
compared in liver slices and isolated perfuse
livers, in the presence or absence of ethanol.
Ethanol depressed the oxidation of all substra
to CO_2; medium-chain fatty acids were much mor
oxidized and reciprocally much less esterified
than long-chain fatty acids, with a 100-fold d
ference in the ratio of esterified lipid-^{14}C t
$^{14}CO_2$. In hepatic microsomal fractions incuba
with α-glycerophosphate, octanoate was much le
esterified than palmitate. This propensity of
medium-chain fatty acids to oxidation rather t
esterification represents a likely explanation
for the reduction in alcoholic steatosis upon
replacement of dietary long-chain fatty acids
medium-chain fatty acids.

10599 COMPARATIVE METABOLISM OF COPPER AND
ZINC IN PATIENTS WITH WILSON'S DISEA
(HEPATOLENTICULAR DEGENERATION). (E.) McCall
J. T. (Mayo Clin., Rochester, Minn.), N. P.
Goldstein, R. V. Randall and J. B. Gross. Ame
J. Med. Sci. 254(1):13-23, 1967.

Data from balance studies on patients with
hepatolenticular degeneration and patients wit
cystinuria showed that admin. of D-penicillami
(250 mg every 8 hr.) altered the metabolism of
both Zn and Cu but the mechanism of action was
not the same for the 2 elements. Urinary Cu
excretion was increased to a max. level in 24
compared to several days for max. Zn excretion
A negative Cu balance was produced by this dru
while the Zn balance was actually more positiv
At the same time the serum Cu conc. was decrea
while that of Zn was not affected. Electropho
studies on the complexes isolated from the uri
of patients before and during ingestion of the
drug showed Cu to be associated with albumin a

3 and γ-globulin, but migration of a stainable
pound was not detected from the point of ap-
cation of Zn compounds. A ninhydrin-positive
compound(s) was detected in the urine but none
e present for Cu. These responses were seen
n in patients who had just begun this therapy
in those who had received D-penicillamine for
long as 8 yr.

00 PRESYMPTOMATIC WILSON'S DISEASE. (E.)
Levi, A. J. (Nat. Hosp., London), S.
rlock, P. J. Scheuer and J. N. Cumings.
cet 2(7516):575-579, 1967.

is important to diagnose presymptomatic Wilson's
ease, since the severe consequences of the dis-
er may be prevented by adequate chelation
rapy. Seventeen children from 5 families hav-
members with Wilson's disease were studied to
ect presymptomatic subjects: 7 had clinical
son's disease, 5 were diagnosed as presympt-
tic (homozygotes) and 5 were thought to be
mal or heterozygotes. Kayser-Fleischer rings
e present in symptomatic, but absent in pre-
ptomatic, patients. All presymptomatic homozy-
es had low serum Cu and ceruloplasmin levels,
these estimations could not distinguish them
h certainty from heterozygotes. The pre-
ptomatic state was confirmed by a liver-Cu
c. (performed on liver needle-biopsy specimens)
r 25 mg/100 g dry wt. Two heterozygotes showed
tually normal liver histology and Cu conc.
son's disease must be positively excluded in
siblings of a proven case, all children who
e had a sibling with cirrhosis and all young
ple with chronic liver disease.

01 HEPATIC BLOOD FLOW MEASURED BY THE
KRYPTON-85 CLEARANCE TECHNIQUE. (E.)
tch, A. G. (Harvard Med. Sch., Boston, Mass.),
H. Casey and R. M. Zakheim. Surgery 62(1):
-180, 1967.

^{85}Kr clearance technic (approx. 0.5 mc, dis-
ved in 0.25 ml saline, was admin. by rapid inj.
2-3 sec. duration) with use of external monitor-
and graphic analysis was applied to hepatic cir-
ation in dogs; 3 or 4 flow rates were consis-
tly found in each curve. Comparing total
patic blood flow calculated from simultaneous
patic artery-portal vein inj. with measured
patic venous efflux, a % of error of ± 16.7% was
und. The av. total hepatic flow in a series of
te dogs was 39.1 ml/kg/min. and in 1 chronic
mal it av. 40.2 ml/kg/min. Clearance after
tal vein, hepatic artery or simultaneous inj.
nonstrated a nonuniformity of blood flow and
ggested the presence of an unshared fast flow
e portal vein component, a shared medium flow
e component and an unshared slow flow rate
patic artery component. Radioautography sug-
sted that the portal vein contribution to the
dium flow rate component may be in the periphery
the lobe, but it failed to localize the other
w rate regions anatomically.

10602 STUDY OF SERUM FATTY ACIDS IN THE COURSE OF HEPATOBILIARY DISEASES. (Fr.)
Warembourg, H. (City Hosp., Lille, France), G. Biserte, M. Bertrand, J. Jaillard and G. Sezille. Rev. Int. Hepat. 17(2):79-86, 1967.

Plasma fatty acid levels and partition of plasma lipid fractions were determined in 41 patients with various hepatobiliary diseases (decompensated cirrhosis of alcoholic origin, 26; jaundice due to viral hepatitis, 9; obstructive jaundice, 6. Patients with cirrhosis showed normal total plasma lipid and free fatty acid levels; plasma free cholesterol, glycerol, and phospholipid levels were normal, while cholesterol ester and sterol fractions showed some decrease. The percentage of oleic acid was increased in all plasma lipid fractions; linoleic acid was decreased in sterol and glycerol fractions; the percentage of saturated fatty acids was decreased in glycerol and phospholipid fractions. In patients with viral hepatitis, plasma total lipid and free fatty acid levels were normal, while the sterol fraction was decreased and the phospholipid fraction increased with respect to controls. Oleic acid percentage was increased and linoleic acid percentage decreased in all fractions in these patients. Among patients with obstructive jaundice, plasma total lipid levels were markedly increased (18.3 g/liter) as compared to controls (5.1 g/liter); sterol levels were markedly decreased (9.4%) with respect to controls (43%); free cholesterol, glycerol, and phospholipid levels were 20, 20.4, and 49%, resp., as compared to 8, 14, and 31.5%, resp., in controls. Oleic acid content was increased and linoleic acid content decreased in the principal lipid fractions of these patients. Although the authors can offer no satisfactory explanation for the findings reported, the different results indicate clearly the abnormal state of blood lipids of these patients.

10603 BLOOD PRESSURE RESPONSE TO ANGIOTENSIN AND NOREPINEPHRINE IN PATIENTS WITH HEPATIC DISEASE. (It.) Morandini, G. (U. Florence, Italy), M. Spanedda and L. Spånedda. Minerva Med. 58(38):1794-1798, 1967.

Pressor response to angiotensin and norepinephrine was studied in 20 patients (13 men and 7 women; age 25-73 yr.) with various hepatic diseases, including cirrhosis with ascites (11), acute hepatitis with jaundice (5), and obstructive jaundice (4). With the exception of 4 patients, arterial blood pressure values in this group were at the lower limit of normality. Results were compared to those obtained in a control group of 20 normotensive subjects (11 men and 9 women; 21-53 yr. old). Pressor response was determined according to the Kaplan-Silah method: patients were kept supine for at least 30 min. during which time i.v. glucose (5%) was admin. slowly until stabilization of pressor values; angiotensin II (1 μg/ml) or L-norepinephrine bitartrate (8 μg/ml), both in glucose soln., were then admin. i.v., the speed of infusion being gradually increased until the diastolic pressure increase became stabilized at 20 mm Hg. The dose of each agent required to obtain this effect was expressed as ng/kg/min. The av. dose of angiotensin and norepinephrine required to raise the diastolic blood pressure 20 mm Hg was 28.8 and 254.8 ng/kg/min., resp., in patients with liver disease as compared to 8.4 and 101.3 ng/kg/min., resp., in controls. The differences were statistically significant. Among the possible explanations for the decreased pressor response in patients with hepatic disease are: vascular hyporeactivity state due to hepatic damage; increased inactivation capacity at the plasma level (only with regard to angiotensin); the development of tachyphylaxis in relation to increased production of endogenous angiotensin (limited only to patients with cirrhosis and ascites).

10604 PLASMA ANGIOTENSINASE ACTIVITY IN PATIENTS WITH HEPATIC DISEASES OF VARIOUS CAUSES. (It.) Morandini, G. (U. Florence, Italy), D. Dimich, P. Manca and M. Spanedda. *Minerva Med*. 58(40):1876-1881, 1967.

Plasma angiotensinase activity was determined according to a method described by Landesman *et al*. in 44 patients (27 men and 17 women; age 14-74 yr.) with various types of liver diseases. The group consisted of 11 patients with acute hepatitis and jaundice, 12 with sclerosing chronic hepatitis, 8 with obstructive jaundice, and 13 with cirrhosis and ascites. Twelve clinically healthy subjects (16-40 yr. old) served as controls. Plasma angiotensinase levels in controls ranged from 80-120%. All but 1 patient with acute hepatitis showed a marked increase in plasma angiotensinase levels (142.82 to 204.48%); in 4 patients, a second determination during the regression phase revealed levels within normal limits. Only 2 patients with chronic hepatitis had slightly increased levels (126.36 and 122.04%, resp.). Plasma angiotensinase levels were also increased in 6 patients with obstructive jaundice (120.33-184.5%) and in 8 patients with cirrhosis (143.25-210.87%). The increase in plasma angiotensinase activity in the above-mentioned patients is attributed to 3 causes: enzyme release due to cytolysis of the damaged hepatic cells; reduced biliary elimination due to cholestasis; increased enzyme production due to greater renin and angiotensin formation as a result of activation of the juxtaglomerular apparatus. Although the presence of increased plasma angiotensinase levels in these patients is an interesting laboratory finding, it does not in itself explain the decrease in blood pressure observed in various forms of hypertension accompanied by liver damage.

10605 SERUM LEVELS OF 5'-NUCLEOTIDASE IN DISEASE. (E.) Eshchar, J. (Chicago Med. Sch., Ill.), C. Rudzki and H. J. Zimmerman. *Amer. J. Clin. Path*. 47(5):598-606, 1967.

To investigate the value of serum 5'-nucleotidase
as a diagnostic tool in liver disease, the spec
ificity and sensitivity of this enzyme were det
mined by the Dixon and Purdom method as modifie
by Kowlessar and associates and Young in 391 pa
tients (280 men and women from 14-91 yr. of age
including 1 infant). Alkaline phosphatase was
measured simultaneously. Patients were dividec
into 5 diagnostic groups: 1) biliary tree ob-
struction (27 patients), 2) parenchymatous live
disease (56 patients), 3) bone disease (25 pa-
tients), 4) combination of 3) with either 1) or
2) in the same patient (9 patients), and 5) mis
cellaneous diseases (274 patients). All patien
(7) with obstructive jaundice showed higher alk
line phosphatase levels more frequently than el
vated 5'-nucleotidase levels (5 of the 7). Lev
of 5'-nucleotidase in biliary tract obstructive
disease were similar to those in parenchymal he
tic disease, and levels in bone disease were
slightly elevated. The level of 5'-nucleotidas
appeared less sensitive than alkaline phosphata
as a measure of hepatobiliary disease.

10606 ABNORMALITIES OF SERUM MONOAMINE OXID
IN CHRONIC LIVER DISEASE. (E.) McEw
C. M., Jr. (NIH, Bethesda, Md.) and D. O. Caste
J. Lab. Clin. Med. 70(1):36-47, 1967.

Serum levels of monoamine oxidase were determin
in 119 adults with acute and chronic liver dise
(13 with viral hepatitis, 17 with infectious mo
nucleosis, 48 with nutritional (alcoholic) live
disease, and 41 with hepatomegaly not attribute
to acute hepatitis or alcoholic liver disease).
Elevated enzyme levels were found in patients w
Laennec's cirrhosis, postnecrotic cirrhosis and
massive neoplastic replacement of the liver, bu
not during the acute phases of hepatitis or ext
hepatic biliary obstruction. The increased enz
activity could not be ascribed to hepatocellula
necrosis or dysfunction. Positive correlations
were found between increased enzyme activity an
signs of portal hypertension and/or portal-syst
collateral circulation. Increased enzyme activ
was most closely associated with hepatic fibros
and "sinusoidal" hypertension, the latter estim
by hepatic vein catheterization. It is conclud
that serum monoamine oxidase may be elevated in
liver disease in the absence of congestive hear
failure.

10607 INTRAVENOUS GALACTOSE TOLERANCE TEST
WITH THE USE OF AN ENZYMATIC METHOD F
THE DETERMINATION OF GALACTOSE. (E.) Tengstro
B. (U. Hosp., Uppsala, Sweden), M. Hjelm, C. H.
De Verdier and I. Werner. *Amer. J. Dig. Dis*.
12(9):853-861, 1967.

A galactose-tolerance test is described, which
a modification of the method of Colcher *et al*.;
galactose is admin. by a single rapid i.v. inj.
or infusion (350 mg/kg); galactose values durin
60-80 min. after the admin. are determined in
capillary blood and form an approx. straight li
in a semilogarithmic system; the result is ex-
pressed as theT 1/2 values for galactose. Gala

erminations are made with a galactose oxidase
nod, the test is simple to perform and the re-
s are reproducible. In a series of 75 tests
healthy students and in patients without sus-
ted liver disease, the value was 12.0 ± 2.6
.; results above 17 min. were regarded as ab-
nal. The test was performed on a clinical
ies consisting of the following: 1) 32 patients
n liver cirrhosis; 2) 11 with acute infectious
atitis, studied within the first 2 wk. of onset
jaundice; 3) 11 with metastatic cancer of the
er; 4) 10 with biliary obstruction, due to a
mon-duct stone in 9 and to cancer of the pan-
as without liver metastases in 1; 5) 49 patients
n a wide variety of diagnoses and with abnormal
ues in 1 or more routine liver function tests
ch as bilirubin values above 1.2 mg/100 ml,
aline phosphatases exceeding 2.6 U, etc.); and
patients without apparent liver disease but with
ditions of interest in connection with gal-
ose metabolism, such as peptic ulcer, diabetes,
. The T½ value was abnormal in 34 (89%) of
tests in patients with liver cirrhosis; of
se, 18 had raised bilirubin values, and 13 of
se had a T½ value above 30 min., which was the
n value for the whole group. Among patients
h hepatitis abnormal findings were found in 5
11 (45%). Seven of 11 (64%) with liver
astases had elevated T½ values. The galactose
value was within normal limits in all patients
h biliary obstruction; the mean value for the
up was 12.9 min. Among the 49 patients with
pected but unconfirmed liver disease, the re-
t of the galactose test was abnormal in 13
%), with T½ values ranging between 17.5-37.5
., and a mean of 24.5 min. The result of the
t in the group of patients with diseases not
marily involving the liver showed abnormal
ults in 5 of 18 (29%) cases of pernicious
mia, 2 of 7 (28%) with sideropenic anemia;
f 17 (47%) with cardiac failure; 5 of 22 (23%)
h hyperthyroidism; 5 of 8 (63%) with hypo-
roidism; and 2 of 21 (10%) with peptic ulcer.
is concluded that this test gives valuable
ntitative information about liver function and
s in the distinction between parenchymatous
obstructive jaundice.

08 COAGULATION METHOD IN AN EXPERIMENTAL
LIVER PUNCH BIOPSY. (Rus.) Bogomazov,
I. (2nd Moscow Med. Inst.). *Eksp. Khir.*
st. 12(2):42-44, 1967.

efulness of the electrocoagulation method for
arrest of hemorrhages from liver parenchyma
thoracic wall soft tissue after liver puncture
psy was studied in 10 rabbits (wt. 2000-2500 g).
ctrocoagulation of the puncture canal was per-
rmed through an external rod covered by Bakelite
plus surgical diathermy. For creation of a
osed electrocircuit inj. needle of a record
ringe was connected with one electrode of the
athermy apparatus and inserted under the skin
the hind foot; the other electrode coming from
diathermy apparatus was connected with a
edle-shaped electric knife. When puncture
biopsy was performed without coagulation of the puncture canal (5 rabbits) hemorrhage from canal lasted 8-10 min. with loss of 15-20 ml blood; the puncture canal was filled with massive blood clots, and liver tissue was infiltrated by blood 1.5-2.0 cm from canal wall. Extensive hemorrhages in the puncture canal and the hepatic tissue surrounding the canal were observed microscopically immediately after puncture biopsy. After 7 days, regenerative changes occurred at the site of puncture canal and after 2 wk. connective tissue scar was present. In the case of puncture biopsy with coagulation of the puncture canal (5 rabbits) blood clots were insignificant, there were no tissue hemorrhages and the surrounding hepatic tissue was of normal color and unchanged macroscopic structure; microscopically there were insignificant hemorrhages. One wk. after puncture biopsy the canal showed necrosis, connective tissue and regenerative processes, while after 2 wk. the puncture site could not be detected. Such puncture with modified Vim-Silverman needle was performed on 85 children with no complications noted.

10609 ABSENCE OF RENAL FRUCTOSE-1-PHOSPHATE ALDOLASE ACTIVITY IN HEREDITARY FRUCTOSE INTOLERANCE. (E.) Morris, R. C., Jr. (U. California Sch. Med., San Francisco), I. Ueki, D. Loh, R. Z. Eanes and P. McLin. *Nature* (*London*) 214(5091):920-921, 1967.

Aldolase activity toward fructose-1-phosphate and fructose-1,6-diphosphate was measured in renal tissue from 6 patients (5 men, 1 woman; 53-73 yr.) with nondiffuse renal disorders and in 1 woman (34 yr.) with hereditary fructose intolerance. Tissue specimens were obtained at surgery; aldolase was measured after Sibley and Lehninger; protein was measured by the biuret reaction. Sample turbidity was corrected by subtraction of optical density at 700 mμ from that at 546 mμ, and the net difference was compared with a standard using bovine serum albumin. Enzyme activities were expressed in terms of μmoles glyceraldehyde/g protein/30 min. Values for fructose-1-phosphate and fructose-1,6-diphosphate, in patients were, resp., renal calculus (22.9; 60.4); multiple renal cysts (17.5; 54.8); renal cell carcinoma (23.6; 63.8); tubular adenoma (22.9; 91.1); papillary cyst adenoma (21.9; 71.9); deformity of renal pelvis (23.2; 71.9); hereditary fructose intolerance (0, 40.3); av. (22.0; 69.7). In human renal cortex, aldolase activity toward fructose-1-phosphate was predictably detectable and was 25-33% that toward fructose-1,6-diphosphate. In hereditary fructose intolerance the values were undetectable and diminished, resp. The results support the hypothesis that renal accumulation of fructose-1-phosphate underlies the renal tubular dysfunction induced by fructose in patients with hereditary fructose intolerance. Hepatic and renal fructose-1-phosphate aldolase seems to be controlled by 1 genetic mechanism. A mixing experiment (mixing tissue homogenates from patients with tubular adenoma and hereditary fructose intolerance) gave no evidence that the inactivity of fructose-1-phosphate aldolase in hereditary fructose intolerance results from an enzyme inhibitor present only in hereditary fructose intolerance or from a lack of an activator present in normal renal cortex.

10610 FRUCTOSE-INDUCED HYPERURICAEMIA. (E.) Perheentupa, J. (U. Helsinki) and K. Raivio. Lancet 2(7515):528-531, 1967.

The effect of i.v. or p.o. fructose (0.5 g/kg) was determined in children with hereditary fructose intolerance (3 boys, 3 girls; 15 mo.-11 yr. old), control children (5; 3 boys and 2 girls; 11 mo.-12 yr. old) and a 26-yr.-old man with essential fructosuria. Uric acid levels in both urine and serum rose sharply, indicating increased uric acid production in controls and children with hereditary fructose intolerance; uric acid levels did not rise in the man with essential fructosuria. The rise was associated with increased lactic acid production. It is suggested that this fructose-induced hyperuricemia is produced by intracellular acidosis in the liver caused by overproduction of lactic acid, and that the uric acid comes from free purine nucleotides, RNA and DNA.

10611 GLYCOGENOSIS TYPE II. GLYCOGEN DISTRIBUTION DISTRIBUTION IN TISSUES. (E.) Hug, G. (U. Cincinnati Coll. Med., Ohio) and W. K. Schubert. Arch. Path. (Chicago) 84(2):141-152, 1967.

Tissue specimens (liver, pancreas, kidney, heart, muscle, brain) from 4 children with classical glycogen storage disease, Type 2, were found to have increased conc. of glycogen and deficient activity of lysosomal acid α1,4-glucosidase. In liver, glycogen content (expressed as % of wet tissue wt.) in the normal was 2.0-6.0, compared to a range of 7.8-12.1 in patients with this disease. Also in the liver, the acid α1,4-glucosidase (expressed as μmoles of glucose liberated from glycogen/min./g of tissue) was 0.183 compared to a range of 0.004-0.023 in patients with this disease. Two types of glycogen were found upon electron microscopic examination of the liver; cytoplasmic glycogen, in which the glycogen was freely dispersed throughout the cytoplasm, and lysosomal glycogen, in which glycogen was tightly packed within the membrane-surrounded structures. The majority of cytoplasmic particles was multigranular (multiparticulate glycogen, glycogen rosettes), whereas the majority of lysosomal particles was monogranular; the diameter of the individual glycogen rosette was up to 150 mμ, whereas the diameter of the individual monogranular particle was 20 mμ or less. Liver tissue obtained at autopsy did not show any cytoplasmic glycogen, while the lysosomal glycogen remained unchanged. Acid phosphatase activity could be demonstrated histochemically beneath the membranes which surrounded the structures containing the lysosomal glycogen. However, not more than 10% showed histochemical evidence of acid phosphatase activity.

In the pancreas, abnormal lysosomes were filled with glycogen to a varying degree; a considerabl number of these structures were empty or nearly so, except for granules sometimes linearly arranged on circular, semilunar or stretched-out fragments of membranes. The varying degree of emptiness of lysosomes in the pancreas may refle an artifact caused by the postmortem diffusion c amylase. While loss of lysosomal enzyme activit may explain the electron microscopic observation of abnormal lysosomes, it cannot account for the excessive accumulation of cytoplasmic glycogen i kidney, heart, skeletal muscle and brain.

10612 MORPHOLOGICAL BASES OF ACUTE AND CHRON INTRAHEPATIC CHOLESTASIS. (Fr.) Sotgiu, G. (U. Bologna, Italy), E. Pisi and G. Cavalli. Arch. Mal. Appar. Dig 56(5):397-407, 1967.

Biopsy studies of several patients with chronic, intrahepatic cholestasis secondary to cirrhosis of the biliary pathways confirmed destruction of both canaliculi and major biliary ducts, apparently resulting from an inflammatory process which involved pericanalicular infiltration of both lympho- and plasmacytes, rupturing of the basal membrane, and progressive degeneration and destruction of epithelial cells. In contrast, i 2 patients with acute intrahepatic cholestasis secondary to viral hepatitis, only an obstructiv cholangitis was evidenced, with obstruction due an inflammatory process involving only epithelia cells. These, in turn, were proliferating activ to a sufficient degree to result in repair of th lesions incurred and reestablishment of normal functioning of the biliary pathways. In this second group of patients, there was no indicatio of any involvement of basal membrane or deformat of biliary ducts.

10613 VASCULAR PERMEABILITY IN EXPERIMENTAL KERNICTERUS. AN ELECTRON-MICROSCOPIC STUDY OF THE BLOOD-BRAIN BARRIER. (E.) Chen, H (Nat. Taiwan U., Taipei), C. S. Lin and I. N. Lien. Amer. J. Path. 51(1):69-99, 1967.

Newborn rabbits were subjected to asphyxiation by exposure to 90 vol. % N_2 for 70 min. and thos which survived (approx. 20%) were given a combin inj. of ferritin and conc. bilirubin soln. (0.3 cc of each) within 30 min. or at 5-hr. intervals following recovery from the asphyxiation, in order to study vascular permeability in experimental kernicterus. This experimental kernicter most often selectively involved the ventral nucl of the thalamus and geniculate bodies whose ultra structure was examined. The endothelial cells appeared to have the same characteristics regardless of whether only ferritin or the combined soln. was inj.: the cytoplasm was moderately dense, containing pinocytotic vesicle a 400-800 in diameter, scanty elements of the endoplasmic reticulum of the rough-surfaced type, a few mitochondria, pairs of centrioles and Golgi compl

most evident change in those inj. within 1
of asphyxiation was an increase in the amount
isible pinocytotic activity in the endothelial
s. These pinocytotic vesicles were larger
the controls and began to take up ferritin
in 0.5-1 hr. after inj. Swelling of the in-
ytoplasmic organelles was reduced in severity
pinocytotic vesicles were decreased in number
the basement membrane showed an increase in
ity 3-4 hr. after asphyxia. Both the mito-
dria and the granular endoplasmic reticulum
med their original size and shape almost com-
ely 4 hr. afterwards. Dense bodies were formed
onsiderable numbers.

4 EXPERIMENTAL HEMOCHROMATOSIS. (Rum.)
Vevera, V., D. Lacky, C. Rădulescu, S.
nianu, D. Capşa and I. Iacob. Fiziol. Norm.
12(6):511-518, 1966.

kept on a protein-deficient diet showed in-
sed amounts of Fe in the spleen, liver, and
rdium and the quantity of Fe was increased
ne liver, spleen, and bone marrow of the
. In male rats, hemosiderin was present in
rgans while in pregnant females, only the
en was significantly affected. The greatest
ts of Fe were found in the tissues of rats
ained on protein-deficient diet supplemented
Fe; within 6 mo. the amounts of Fe in the
n and liver of these animals was twice the
l and plasma transferrin was fully saturated
μg%). Rats maintained on a purine-rich diet
emented with vitamin B presented normal Fe
ption, with sideremia varying between 150 and
g% and free transferrin amounting to 150-200
Both males and females had slight tissue
ntation while Fe was significantly increased
e liver and bone marrow of the fetus. In
maintained on a protein-diet supplemented with
d vitamins, the Fe absorption was significantly
than in the animals maintained on a protein-
ient diet. Liver hemosiderin was lower in
ant females than in male rats while intense
ntation was present in fetal tissues. Re-
were confirmed histologically, biochemically
the amount of radioisotope uptake.

AMEBIC LIVER ABSCESS. (E.) Dorrough,
R. L. (Wallace Mem. Baptist Hosp., Pusan,
. Southern Med. J. 60(3):305-310, 1967.

arison of 22 (21 males, 1 female) Korean
of amebic liver abscess and 23 (21 males,
les) Atlanta (Georgia) cases emphasized the
stic disparity between the American and the
c groups. The clinical entity of amebiasis
readily recognized in this country, thus
erican group showed greater chronicity,
ity and mortality. Amoebas were found in
ools of 3 Koreans and 1 American. The
inantly younger male (veteran) Atlanta cases
in age from 7-87 yr. old. Various forms
causative amoeba were found in only small
s in both groups. Other parasites were more frequent in the Korean group. Of the Koreans, 17 had right lobe abscess, 4 had left lobe abscess, 1 had both lobes involved, and 3 had multiple abscesses. Of the Americans, 21 had right lobe abscess, 1 had left lobe abscess, and 1 had multiple abscesses. Diagnostic delay after hospitalization was 2.1 days in Korea and 14.9 days in Atlanta. More complications and deaths occurred in the Atlanta group, that is, only 9.1% in the Korean, but 26.1% in the Atlanta group. Diodoquin is indicated for intestinal amebiasis, with emetine and/or chloroquine for the liver abscess, and supportive broad-spectrum antibiotics. Right lobe aspiration is indicated in uncomplicated cases. With the suggested combination therapy, various previous authors reported: 1) 2% mortality, 2) 3.6% mortality, 3) no deaths in 75 consecutive cases, and, in general, low complication rate for aspirations. Complications of the abscess require special therapy, as do abscesses in the other lobes.

10616 THE EFFECTS OF CONGESTION ON CERTAIN LIVER TISSUE CONSTITUENT WEIGHTS. (E.)
Souser, R. C. (Woman's Med. Coll. of Pennsylvania, Philadelphia), A. L. Edelstein, B. Sigel and H. Menduke. Arch. Surg. (Chicago) 95(2):217-219, 1967.

White Sprague-Dawley CD strain rats (40 males, 20 females) were divided into 2 groups: 1) control animals had a laparotomy, section of the falciform ligament and isolation of the inferior vena cava cephalad to the liver; and 2) test animals had the identical procedure but, in addition, the vena cava was ligated to produce acute liver congestion. The effect of liver congestion upon liver tissue dry wt., fat extracted dry wt., total protein and DNA content was determined. In no instance was there significant interaction between congestion and sex; i.e., there was no evidence that the effect of congestion was any different in males than it was in females. In terms of wet wt., the congested livers were 40% heavier than the control; this difference was reduced to 20% and 23% in terms of dry and fat-extracted dry wt., resp. An increase of 35% in the protein content was observed in the congested liver; this was comparable in magnitude to the increase in wet wt. Congestion influenced the DNA content least; an 11% increase was observed in DNA content in the congested liver. All of these differences were statistically significant. It is concluded that congestion not only increases the wet wt. of liver tissue but also other commonly employed measures (dry wt., fat extracted dry wt., protein and DNA). This experiment emphasizes that a direct measure of cell division is important in experiments where liver regeneration is being appraised.

10617 TOPOGRAPHY OF BLOOD VESSELS AND BILE DUCTS IN THE PORTA OF THE LIVER. (Rus.)
Umbrumiants, O. A. (Sechenov 1st Moscow Order of Lenin Med. Inst.). Vestn. Khir. Grekov. 98(6): 52-57, 1967.

In 49 isolated liver preparations a conditional division of hepatic porta into the region of a hepatoduodenal ligament and of Glisson's pedicles of the hepatic lobes was done for a more precise determination of each variant for different surgery. Portal vena, hepatic artery, and bile ducts were persistent elements of the hepatoduodenal ligament. A typical division of the general stem of the portal vein into right and left vein was found in 42 of 49; in 3 it was divided into left, right paramedial, and lateral vein; in 3 there was proximal displacement of the right lateral vein; e.g., the latter branched out early from the general stem which was divided at the usual site into left vein and right paramedial vein. Therefore, in all these variants, the right vein was absent and replaced in the right lobe by 2 and 3 veins; this should be considered during resection of the right lobe to prevent dangerous hemorrhage. The diminution of the length of general stem of the portal vein with proximal displacement of the right lateral vein should be considered in establishment of portacaval anastomosis. The general stem of the portal vein was located in all preparations at the back of the hepatic artery and bile ducts and headed sideways from left to right and from down up. Bile ducts were located in most preparations at the front and from the hepatic artery, only in 2 cases did the right artery pass at the front of the common hepatic duct. Typical formation of the common hepatic duct from right and left ducts occurred at the level of bifurcation of the portal vein in 32 of 49; in 7 the common hepatic duct was formed from the left duct and right paramedial and lateral ducts showing some variants; in 3 distal displacement of the right paramedial duct was found and distal displacement of the right lateral duct occurred in 4. The hepatic artery was located in all cases at the left end of the hepatoduodenal ligament and headed sideways from left to right. In 28 of 47 the hepatic artery was divided into left and right artery; in 19 the left hepatic artery was absent; in 15 the corresponding artery for segments 2-3 and artery of segment 4; in 4 initially artery of segment 4 and then artery of segment 2-3. In the region of Glisson's pedicles of the hepatic lobes the following variants were observed; in 2 cases transposition occurred from right to left of the right paramedial vein in which it branched out atypically from the left vein; in 2 cases transposition occurred of the right lateral duct and of the duct of segment 7 from right to the left; in both cases indicated the ducts fell atypically into the left duct.

10618 THE SIGNIFICANCE OF BILIARY PRESSURE. (E.) Williams, R. D. (U. Texas Med. Branch, Galveston), J. C. Fish and D. D. Williams. Arch. Surg. (Chicago) 95(3):374-379, 1967.

Biliary pressure was measured with varying degree of obstruction of the common bile duct in dogs; simple obstruction caused little liver damage, dilatation of the extrahepatic ducts and bile pressure elevations related to the degree of obstruction. Pressure elevations were related
the degree of obstruction; pressure required to
elevate serum alkaline phosphatase was less tha
that for bilirubin. Once the bile ducts became
dilated, they remained so although pressure, se
bilirubin level and alkaline phosphatase return
to normal. Infection added to the experimental
obstructed and dilated biliary tract usually ha
no effect on bilirubin or alkaline phosphatase,
but it increased liver damage. Infection occasionally increased existing obstruction. It
prevented dilatation of the extrahepatic ducts
induced simultaneous with obstruction. This re
lationship between obstruction, infection and duct changes warrants more careful clinical observations. Although cholangitis may produce jaundice by liver damage, it usually does so by
increasing obstruction. A review of 200 cases
with jaundice and cholecystitis showed that in
the absence of obvious obstruction of the bile
ducts, thorough exploration and liver biopsy a
indicated.

10619 EXCHANGE TRANSFUSION IN THE TREATMENT OF ACUTE LIVER FAILURE: A PRELIMINARY REPORT. (E.) McKechnie, J. C. (Meth
Hosp., Houston, Tex.), P. S. Bentlif, J. P. Abbott and J. R. Kelsey. Southern Med. J. 60(3):297-300, 1967.

Three cases of severe hepatic coma treated wit
exchange transfusion are described. In the fi
case, an 18-yr.-old white female who had presented with ascites and peripheral edema, the
level of venous blood at the height of deep co
was 264 µg%, compared with a control of 40 µg
She was treated with 1 exchange transfusion of
10 U of fresh oxalated blood; venous blood NH_3
fell to 94 µg%, and coma persisted for 3 days
after exchange. The patient was dismissed in
improved condition, but with elevated bilirub
The second case, a 37-yr.-old white male with
hepatitis (who had received a renal transplan
yr. previously) was treated with 2 exchange t
fusions of oxalated blood. Venous blood ammo
fell from 236 µg% to 100 µg% after the first
transfusion, and he was alert 4 hr. after the
first exchange. The patient died on the seco
day, in hepatic and renal failure. In the th
case, a 55-yr.-old white male was admitted in
severe hepatic coma, with a venous blood NH_3
of 129 µg%; he was treated with 1 exchange tr
fusion, but had no recovery and died, still i
coma, 3 days later, with a level of venous bl
NH_3 of 114 µg%. Massive hepatic necrosis was
evident at autopsy, and was thought to have b
halothane-induced. The experience reported h
compares favorably with the experience of 14
reported cases. It is concluded that exchang
transfusion deserves further evaluation as a
method of treatment in cases of infectious he
titis with supervening hepatic coma and in se
cases of chronic liver disease with potential
reversibility.

0 HEPATIC COMA DUE TO ACUTE HEPATIC NECROSIS TREATED BY EXCHANGE BLOOD-

SFUSION. (E.) Jones, E. A. (Roy. Free Hosp., on), D. Clain, H. M. Clink, M. MacGillivray S. Sherlock. Lancet 2(7508):169-172, 1967.

n patients (3 males, 4 females; 5-68 yr. old) epatic coma due to acute hepatic necrosis were ted with exchange transfusions using 5-58 liters resh blood/patient. In adults, 3-9 liters were nged in any 1 day, and there were 2-15 ex- es on each patient. In 4 patients, the acute ic necrosis was due to virus hepatitis; in 2, llowed multiple exposures to halothane, and it was associated with therapy with a mono- -oxidase inhibitor, phenelzine. Three pa- s showed striking improvement in the level nsciousness and in 2 of these and 1 other was unequivocal improvement in the electro- halogram. Three patients had severe oliguria. patients ultimately died. Initial improve- in the prothrombin-time was not always main- d. Thrombocytopenia was progressive. A e bleeding tendency developed or persisted in atients. The 5-yr.-old child had the most ing improvement in the level of consciousness treatment. In 6 cases, liver histology at sy showed recent gross necrosis of liver and distortion of the hepatic architecture condensation of reticulin to such a degree if survival had followed, macronodular cir- would have been inevitable. In 4 patients, wt. at necropsy was decreased, in 2 to very vels.

FIFTEEN YEARS' EXPERIENCE WITH PORTO-SYSTEMIC VENOUS SHUNTING OPERATIONS.

Foster, J. H. (U. Oregon Med. Sch., Portland) M. Vetto. Amer. Surg. 33(7):514-519, 1967.

erall operative mortality rate after 47 ve portosystemic shunts was 19% and after rgency shunts it was 55%. The 2 most im- t factors in patient survival were found whether the patient was a chronic alcoholic ether the operation was done as an emergency. r, the alcoholic patient survived elective ystemic venous shunting almost as well as nalcoholic, but the long-term survival was icantly decreased in the alcoholic. Age t make a significant difference with elec- erations (av., 49 yr.) but in the emergency (av., 53 yr.) the mortality rate was higher younger patients. Of the 21 operative 15 were alcoholics; cause of death was hemorrhage during surgery in 7 cases, re- esophageal hemorrhage in 2, protracted and/or hemorrhage related to a splenectomy ses and liver failure in 8 cases. Over a of 6 wk.-12 yr., 13 of 40 patients who llowed died; of these, 10 were alcoholics. patients followed, 78% who had elective enal shunting experienced massive recur- morrhage while, conversely, no patient who d elective portacaval shunting had any of rebleeding after hospital discharge.

10622 A RETROPANCREATIC PORTAL-SYSTEMIC SHUNT FOR PORTAL HYPERTENSION IN CHILDREN.

(E.) Martin, L. W. (U. Cincinnati, Ohio). Arch. Surg. (Chicago) 95(3):332-338, 1967.

A retropancreatic portal-systemic shunt is described in which the portal vein is anastomosed to the left renal vein or to the vena cava; this procedure was used in 6 children (1 boy, 5 girls; 14 mo.-9 yr. old) with bleeding esophageal varices and an extrahepatic block of the portal vein, and satisfactorily accomplished portal decompression in each patient. Three variations were used; in 1 case, anastomosis was side-to-side, in 2 the portal vein was anastomosed to the vena cava at its point of junction with the left renal vein, and in 3 the anastomosis was between the end of the portal vein and the side of the left renal vein. In each case, there was a satisfactory fall in portal pressure after operation; the results of a fructose tolerance test, done in each case before and after the procedure, indicated patency of the shunt. There were no complications of the operation and no further bleeding for as long as 4.5 yr. after the operation. This operation is done in an area of minimal collateral vessels, and is in striking contrast to the extreme vascularity and excessive blood loss often encountered during the course of a conventional portacaval or splenorenal shunt operation. A serious potential complication of the operation could be thrombosis of the anastomosis resulting in superior mesenteric venous thrombosis and necrosis of the entire midgut. It is concluded that while the shunt is difficult to perform, it may be life-saving in selected cases where other type shunts are not feasible or have failed.

10623 PERFUSION OF THE LIVER FOLLOWING SIDE-TO-SIDE PORTACAVAL SHUNT. (E.)

Britton, R. C. (Columbia U., New York, N. Y.), A. B. Voorhees, Jr. and J. B. Price. Surgery 62(1):181-188, 1967.

A total of 12 patients (6 male, 6 female; 21-72 yr. old; 11 with cirrhosis and 1 with the Budd-Chiari syndrome) were studied by simultaneous catheterization of the hepatic veins and the hepatic portal veins from 2 wk.-10 yr. after side-to-side portacaval shunt operations. All patients had retrograde hepatic portal flow which was estimated by cineangiography to range from 318-1075 ml/min., with an av. of 668 ml/min. Corrected hepatic vein flows ranged from 27-571 ml/min., with an av. of 246 ml/min. Although the av. percentages of extraction of BSP, O_2, and ammonium were larger from hepatic vein blood than from retrograde portal blood, the av. removal rates of these substances and glucose release from the liver were larger by the retrograde portal route. These findings suggest that retrograde portal flow after side-to-side shunt may result in less efficient perfusion than by the hepatic vein route but that retrograde portal perfusion is quantitatively significant and may be superior in some patients to hepatic vein perfusion.

10624 PREOPERATIVE ASSESSMENT OF PORTAL HYPERTENSION. (E.) Warren, W. D. (U. Miami Sch. Med., Fla.), J. J. Fomon, M. Viamonte and R. Zeppa. Ann. Surg. 165(6):999-1012, 1967.

Hepatic and splanchnic vascular physiologic features were studied preoperatively in 74 patients with either cirrhosis of the liver or presinusoidal portal vein obstruction. Methods used involved estimation of total hepatic blood flow with ^{198}Au, liver-spleen scan, hepatic vein catheterization, splenoportography or indirect portography, visceral angiography and in several cases, umbilical vein catheterization. Splenoportography was the most useful single examination procedure in the preoperative assessment of portal hypertension; with this technic it was possible to establish the diagnosis of portal hypertension, locate collateral veins, including esophageal varices, estimate the vol. of intrahepatic and extrahepatic portal venous flow, and establish the patency, but not occlusion, of the portal vein. Splenoportography was also the best way to grade esophageal varices and assess portal venous flow to the liver. Catheterization of the hepatic vein was especially valuable for study of the seriously ill patient; with both manometric and venographic studies, it was possible to effect the diagnosis of portal hypertension and differential diagnosis of intrahepatic from extrahepatic obstruction of the portal vein, assess portal venous flow to the liver and obtain a definitive differential diagnosis between occlusive obstruction and spontaneous reversal of flow in the portal vein. Characteristic patterns with hepatic venography were identified which clearly delineated either very good or very restricted portal venous flow to the liver. Determination of pressures in the basal state was helpful in interpreting pressures measured during operation. The ^{198}Au technic for estimation of hepatic blood flow showed significant differences between mild (or early) and severe portal hypertension; it was most useful in screening patients with near normal or very low hepatic blood flow. Liver-spleen scan was helpful in assessing the significance of extrahepatic uptake of ^{198}Au in individual patients. Visceral angiography with indirect portography was most useful in postsplenectomy patients and when splenoportography was contraindicated. The ability to define precise vascular physiologic changes in individual patients with portal hypertension is becoming clinically very important.

10625 TRANSUMBILICAL PORTAL DECOMPRESSION. (E.) Piccone, V. A. (Brooklyn VA Hosp., N. Y.) and H. H. LeVeen. Surg. Gynec. Obstet. 125(1):66-72, 1967.

The feasibility of transumbilical portal-systemic shunting for relief of portal hypertension was examined. Anatomic studies on cadavers and clinical studies confirmed previous reports that the umbilical vein is easily reopened to an unexpectedly large caliber and is a direct connection to the main portal flow (by connection with the left branch of the portal vein). High flow rates we
obtained from umbilical catheters in patients
undergoing transumbilical hepatoportography.
Temporary and permanent transumbilical portal-
systemic shunts were constructed in patients wi
portal hypertension, and decompression of the
hypertensive portal system was achieved. A
temporary shunt with a plastic connector and th
portal-systemic pressure gradient was used in 3
patients (for up to 3 days); no ascites or hemo
rhage occurred and portography was successfully
achieved. A temporary shunt using a pump was u
in 2 patients, and flow rates of 450 cm^3 were
easily achieved. Permanent transumbilical port
systemic shunting was achieved in a cirrhotic
patient (46 yr. old) with portal hypertension,
bleeding esophageal varices and ascites poorly
controlled by spironolactone, hydrochlorothiazi
and a low salt diet; the reopened umbilical vei
was anastomosed to the saphenous veins. There
was a reduction of portal pressure from 43 to
cm of H_2O, postoperative angiographic demonstra
tion of the shunt, the obviously patent dilate
vessels clearly visible on the abdominal wall,
cessation of gastro-esophageal bleeding and la
of further ascitic formation in spite of discontinued diuretics and spironolactone. It is
concluded that transumbilical portal-systemic
shunting, temporary or permanent, can offer de
compression with a relatively minor surgical p
cedure. The technic herein described represen
the first use of the reopened umbilical vein o
the adult for portal decompression.

10626 EXPERIMENTAL DATA WITH REGARD TO
SURGICAL TREATMENT OF COMPLICATED F
OF PORTAL HYPERTENSION. (Rus.) Matiugina, 0.
(Gorkii Kirov Med. Inst., USSR). Vestn. Khir.
Grekov. 98(6):71-73, 1967.

Observation of 200 operated animals with esta
ment of different anastomoses by vascular sut
apparatus, showed that venous anastomoses of
mm diameter (in dogs) were the most effective
valuable, while mesenteric-femoral anastomosi
was the most advantageous and could be perfor
by 5 variants. In 95 with mesenteric-femoral
anastomosis performed the most expedient were
variants 1, 2, and 5, when for anastomosis th
central end (Variant 2) was taken, or both en
of the upper mesenteric vein (double mesenter
femoral anastomosis; variant 5), or the perip
end of upper mesenteric vein (Variant 1). In
single cases the femoral vein was sutured wit
of the largest branches of the upper mesenter
vein (Variant 3), and also a T-forming conne
of the peripheral end of upper mesenteric ve
with the femoral or end of the femoral with
enteric vein (Variant 4) was performed. Con
tion of the lower mesenteric vein is possibl
mainly by 3 variants (e.g., connection of th
peripheral or central end of the mesenteric
with the femoral vein, or double mesenteric-
anastomosis); T-forming connection with a sm
diameter of stem is accomplished in the femo
vein in the presence of the large stem, this

le also in the mesenteric vein. Mesenteric-
nastomoses is possible by end-to-end and
pe of T-forming anastomosis of mesenteric
enal and renal into mesenteric. Mesenteric-
nastomosis is confined to the length of
ein and is possible in only 1 variant with
ipheral end of the upper mesenteric vein.
ages from varicose veins of the esophagus

PHARMACOLOGIC CONTROL OF PORTAL HYPER-
TENSION. (E.) Nusbaum, M. (U.
vania, Philadelphia), S. Baum, P. Sakiyalak
S. Blakemore. Surgery 62(2):299-310, 1967.

ve infusions of several pharmacologic agents
de into the superior mesenteric artery in
of dogs with experimentally constructed
hypertension (which was induced by inj.
heres of 12-35 μ of styrene divinylbenzene
er latex directly into the portal vein).
rine (1 μg/kg/min.), norepinephrine (0.191-
/min.) and angiotensin (0.191-1.0 μg/min.)
lar effects of constriction of the splan-
essels and decrease in portal inflow but
resulting increase in portal outflow re-
and portal hypertension. These agents
sustained portal hypotensive action. Vaso-
(0.019 pressor U/min.-0.382 pressor U/min.)
pressin derivatives, were utilized in
ve infusion and found to produce splanchnic
sm with a decrease in superior mesenteric
portal inflow with a resulting decrease
l pressure. Vasopressin in the dosage
vided a sustained portal hypotensive ac-
en continuously infused. The efficacy
dosages of vasopressin and its derivatives
usly infused through the superior mesen-
tery in achieving a prompt and sustained
the portal pressure was demonstrated.
ressure was decreased 50% in the portal
sive dog and 20% in the normal dog. No
in cardiac output were observed during
sion of vasopressin; no evidence of ischemic
were found in the organs studied by histo-
examination; blood-gas studies of portal
rior mesenteric blood before and during
sin infusion showed no significant change.
A concomitant decrease in superior mesenteric flow av. 58%. A relatively easy and effective method of decreasing portal pressure utilizing technics developed for selective arteriography is given, with a plan for the clinical application in the management of hemorrhage associated with portal hypertension and varices (esophageal).

10628 S-ADENOSYLMETHIONINE FOLLOWING PORTACAVAL ANASTOMOSES. (E.) Baldessarini, R. J. (NIH, Bethesda, Md.) and J. E. Fischer. Surgery 62(2):311-318, 1967.

After end-to-side, but not side-to-side portacaval shunts, adult male Osborne-Mendel laboratory rats were found to have smaller livers, with a decrease of S-adenosylmethionine, both in conc. and total amount. These metabolic defects did not appear in the brain. The livers were not deficient in the enzyme which produces S-adenosylmethionine. When exogenous substrate, methionine, was admin., the livers of rats with portacaval shunts responded quite strikingly to synthesize S-adenosylmethionine. It is suggested that a major factor in producing this chronic metabolic defect is the lack of dietary substrate due to the shunting of substrate-rich portal blood away from the liver. Portal-systemic anastomoses which retain some portal blood flow, while reducing portal hypertension, may produce less hepatic metabolic damage. Moderate dietary supplements of methionine may be of benefit to patients after portacaval anastomoses.

10629 A REVERSE PORTACAVAL ANASTOMOSIS UNDER EXPERIMENTAL CONDITIONS. (Rus.) Bazhenov, V. S. and V. S. Perlin. Eksp. Khir. Anest. 12(2):38-39, 1967.

In 12 dogs observed up to 700 days following establishment of reverse portacaval anastomosis, surgery was followed immediately by exacerbation, urine showed up to 1.85% proteins, in blood, albumin av. decreased to 3.96 mg% and urea av. increased to 25.8 mg%; however, later these indices were normalized. The pressure in s.c. veins of the forearm remained unchanged, while in the inferior vena cava, the av. pressure increased to 201 mm H_2O, and in mesenteric and splenic vein it increased to 184 and 182 mm H_2O. The velocity of portal blood flow and blood flow through the superficial veins of the front and hind leg decreased to 81.5, 24.1 and 36.2, resp., but was subsequently normalized in the first 2; in the last one it remained somewhat delayed for a prolonged time. Reaction to i.v. admin. of lobeline after surgery occurred only after increased doses (up to 5 ml), but could be due to partial destruction of lobeline in the liver. Therefore, reverse portacaval anastomosis was well tolerated and hemodynamic and biochemical blood changes were reversible. Such an anastomosis could be used in clinic, while also being useful in experimental, conditions on the study of the action of different medicinal and toxic compounds directly on liver by their admin. into the hind leg superficial vein.

10630 THE ROLE OF PORTAL BLOOD IN REGENERATION AND FUNCTION OF COMPLETELY REVASCULARIZED PARTIAL HEPATIC AUTOGRAFTS. (E.) Price, J. B., Jr. (Columbia U., New York, N. Y.), A. B. Voorhees, Jr. and R. C. Britton. Surgery 62(1):195-203, 1967.

Partial hepatic autotransplantation using complete transplant revascularization was combined with a 30% hepatic resection in 135 dogs; a control segment with relatively undisturbed blood supply and biliary drainage was present in each animal. Twenty-eight animals survived for at least 6 days, and 8 animals survived for more than 4 wk. One group received mesenteric blood through the transplant portal vein and good transplant regeneration occurred. A second group received caval blood through the transplant portal vein, and slow atrophy was observed. Animals with thrombosis of the portal-vena caval anastomosis showed more rapid atrophy. In spite of receiving portal blood, a transplant with complete bile duct stenosis showed marked atrophy. Ammonia and BSP extractions and glucose release from both segments were compared by sampling with simultaneous hepatic vein catheterization; the atrophic segments showed decreased function in comparison with their normally functioning controls. It is concluded that substances present in portal blood have at least a permissive role in determining hepatic regeneration and function in a system with competing hepatic segments. The feasibility of partial hepatic transplantation has been demonstrated by this study.

10631 PARTIAL HEPATIC AUTOTRANSPLANTATION WITH COMPLETE REVASCULARIZATION IN THE DOG. (E.) Price, J. B., Jr. (Columbia U., New York, N. Y.), A. B. Vorrhees, Jr. and R. C. Britton. Arch. Surg. (Chicago) 95(1):59-64, 1967.

Of 130 mongrel dogs subjected to partial hepatic autotransplantation with complete revascularization using either portal vein or inferior vena caval blood for perfusion, 36 dogs survived over 3 days postoperatively. The longest survivor was in good health at 9 mo., postoperatively. Transplantation involved the left central and lateral lobes with the right lobes being left intact. Liver regeneration was stimulated by resection of the central lobes. Outflow block phenomena accounted for 25% of the fatalities, while pneumonia with or without intussusception, esophageal perforation or peritonitis accounted for another 50%. Thrombosis or twisting of the hepatic vein anastomosis occurred early after operation and resulted in rapid death. Edema of the transplant usually occurred on the fourth or fifth postoperative day and was less marked in those dogs who had undergone operative hypothermia. Both types of revascularization resulted in long-term survivors with good liver function. Autotransplants of the portal-superior-mesenteric group showed good regeneration and liver function, while atrophy of the transplant was consistently observed in transplants receiving no venous blood supply. SGOT values normalized within 2 wk. in long-term survivors after an initial sharp postoperative rise.

10632 ALLOGENIC CANINE LIVER TRANSPLANTATI
WITH CADAVER DONORS. (E.) Fonkalsr
E. W. (UCLA Sch. Med., Los Angeles, Calif.),
H. Ono, O. A. Shafey, W. L. Joseph, J. Tocorna
and W. P. Longmire, Jr. Surgery 62(2):333-339
1967.

Hepatic allografts obtained from cadaver donor
were transplanted orthotopically in 15 dogs an
heterotopically in 9 dogs in order to study th
technical problems which could be anticipated
in clinical liver transplantation. Extracorpo
perfusion was used while the donor liver was e
cised; asanguinous hypothermic perfusion of th
graft was performed until the venous effluent
clear. Only 2 dogs survived longer than 48 hr
after transplantation. Prolonged hepatic isch
resulting in cellular disruption and venous co
gestion appeared to the major cause of death.
Inadequate hepatic perfusion during and after
transplantation may have also hastened death.
Hypotension immediately following hepatic veno
declamping and restoration of blood flow to th
graft seemed to be related to the release of
dentified metabolites into the circulation.
pressors and bicarbonate were only of tempora
benefit in correcting shock, even in animals
ceiving heterotopic grafts. Additional studie
to evaluate the feasibility of cadaver liver
transplantation in dogs and other species wou
appear to be indicated before extensive clini
trials of liver grafting are performed.

10633 ORTHOTOPIC CANINE LIVER HOMOTRANSPL
TION WITHOUT VENA CAVAL INTERRUPTIO
(E.) Fonkalsrud, E. W. (U. California, Los
Angeles), H. Ono, O. A. Shafey and W. P.
Longmire, Jr. Surg. Gynec. Obstet. 125(2):31
327, 1967.

Hepatic allografts were transplanted orthotop
in 25 adult mongrel dogs without interruption
the recipient's vena cava or use of external
vascular shunts for splanchnic decompression.
The donor dogs were anesthetized and the av.
of hepatic anoxia was 55 min. The portal vei
and hepatic artery of the graft were perfused
with hypothermic buffered Ringer's lactate so
until the venous effluent was clear. Twenty-
of 25 dogs survived at least 24 hr., and 7 li
for more than 1 wk. The longest survival per
were 94 and 106 days. Biochemical studies we
not helpful in distinguishing graft rejection
from hepatocellular injury due to azathioprin
Similarly, upon histologic study, it was diff
to define clearly changes which were immunolo
mediated from those caused by mechanical phen
ena or drugs. Mononuclear cell infiltration
usually seen with rejection was not prominent
the livers of animals that died 3 wk. or more
after transplantation. Hepatic venous outflo
obstruction appeared to be directly related t
the duration of hepatic anoxia during transpl
tion and was 1 of the major factors causing e
death in the dogs. Hypothermic perfusion of
liver with buffered electrolyte soln. during

d of ischemia appeared to reduce the severity
's complication and to permit longer periods
atic anoxia with return of liver function.
rition and sepsis were the leading causes
th in dogs who lived more than 3 wk.

HOMOTRANSPLANTATION OF THE CANINE LIVER
AS AN ORTHOTOPIC VASCULARIZED GRAFT.
Baik, T. Y. (Pusan Nat. U., Coll. Med.,
, Y. D. Kim, C. W. Eun, E. S. Park and Y. U.
J. Korean Med. Ass. 9(8):693-702, 1966.

een liver homotransplantations were performed
34 healthy mongrel dogs of about 20 kg wt.
17 survived for more than 2 hr.; 1 for 2 hr.
min. and the other for 13.5 hr. Autopsy
ed pulmonary embolism, cardiac infarction,
clots in the right atrium and ventricle,
intestinal hemorrhage and a markedly con-
liver in all the dogs. In these homo-
lantation experiments, 3 new technics have
evised. 1) A method anastomosing anteriorly
osterior aspects of the posterior walls of
ferior vena cava stumps below the recipient's
agm and above the transplanted liver. In
rocedure, the Kelly forceps which clamped
ne recipient diaphragm and the stump of
or vena cava were pulled outside the peri-
cavity so as to turn the posterior aspect
posterior wall of its vessel foreward. 2)
structing the extracorporeal bypass, the
l end of the polyethylene tube was directly
ed into the visceral stump of the portal vein
renal stump of the inferior vena cava.
e the stumps maintain venous return to the
anastomoses were carried out between both
veins of the transplanted liver and the
nt, and between the inferior vena cava of
nsplanted liver and the recipient. It is
led that these procedures shorten the cir-
y blocking time to the utmost limit, and
trauma to a minimum.

TEMPORARY EXTRACORPOREAL USE OF HETER-
OLIVER IN REANIMATION OF PATIENTS WITH
EPATIC INSUFFICIENCY. (Rus.) Savitskii,
Kirov Order of Lenin Med. Acad., Leningrad,
A. P. Kolesov, F. V. Balliuzek, M. O.
, V. I. Skorik, I. M. Markelov and Z. K.
Vestn. Khir. Grekov. 98(5):75-80, 1967.

meability of cellular membranes of heterol-
iver during hypoxia, conditioned by technical
antation (in large donor cats, ligation of
erior vena cava, hepatic artery and common
ct, isolation of the liver, washing, cool-
tracorporeal connection to femoral vessels
recipients, dog, monkey), was evaluated
activity of isoenzyme LDH in the donor
control) and in perfusate after different
of hypoxia. One hr. of hypoxia caused
ance of the permeability of cellular
es and discharge of LDH_5 from liver cells;
ctivity of LDH of donor blood before ex-
of liver was 0.38-0.45 μM/ml/min. substrate,
while LDH activity in the perfusate after 1 hr. of hypoxia was 0.95-1.0 μM/ml/min. substrate. After reduction of hypoxia to 25-30 min. permeability of cellular membranes was not affected. For the preservation of the structure and function of hepatic cells during liver washing the time of hypoxia, and the technic of perfusion are important; e.g., perfusate pressure in the portal vein should not exceed 160 mm H_2O column, osmotic pressure of perfusate (gelatinol basic ingredient) should be 300-315 mosmoles/liter, and pH 7.3-7.4. Immunologic activity of heterologous liver studied in 3 dogs and 1 monkey with extracorporeal connection of cat liver for 3 hr. showed an absence of complement-fixing antibodies to the antigen of cat liver, and intracutaneous admin. of allergen did not induce a positive allergic reaction. In clinical study the connection of donor heterologous liver (large young dogs), isolated by the above method, could be artery-vena (at least profitable due to possible severe hypotension), vena-vena and vena-artery (most expedient) with the help of apparatus for artificial circulation. For connection of the heterologous liver with the perfusion apparatus it is sufficient to use the femoral vein for intake and the large s.c. vein of the hand or leg for return. Temporary extracorporeal connection of heterologous liver was accompanied in all 4 patients (1 with hepatic and 3 with hepatorenal insufficiency) by temporary improvement in general condition and biochemical indices [in blood bilirubin, residual N and free hemoglobin (at hemolysis) content was reduced, aspartateamino- and alanineaminotransferase activities were decreased, and, in some, indices of acid-alkaline condition were normalized]. With an absence of irreversible damage in vital organs and systems the temporary use of heterologous liver is effective for reanimation of patients with acute hepatic insufficiency. All 4 patients (2 males, 2 females, age 12-56 yr.), discussed in detail, died, 3 showing irreversible changes of vital organs and systems.

0737 ALTERATIONS IN SERUM NAPHTHYLAMIDASE ISOZYMES DURING TREATMENT WITH ORAL ONTRACEPTIVES. (E.) Arturson, G. (U. Uppsala, eden), L. Beckman and B. H. Persson. Nature ondon) 214(5094):1252-1253, 1967.

electrophoretic studies, a significant increase serum naphthylamidase B activity, a zone ich migrates more slowly than naphthylamidase and which is electrophoretically indistin- ishable from the naphthylamidase pregnancy zyme, oxytocinase, was found in 18 of 34 women o had been taking oral contraceptives for riods of 3 mo. - 3 yr. A similar increase was monstrable in only 1 of 31 controls, who was und to be pregnant. When incubated with bbit antiserum, sera with strong naphthylamidase activity in the presence of severe burn or eatment with either phenothiazine or oral ntraceptives lost all activity in zones A, B d C, although the B zone remained unaffected in egnancy sera incubated in the same way. It is ncluded that the increase of serum naphthyl- idase B activity in some patients receiving al contraceptives appeared to represent a nspecific indication of liver damage or distur- nce of liver metabolism. Both the absence of discernible dose-response relationship and the ilure of some individuals to develop the action suggested the further possibility that sceptibility to these compounds was genetically termined.

0738 MATRIX INCLUSION BODIES IN THE MITOCHONDRIA OF THE HUMAN LIVER. EVIDENCE F HEPATOCELLULAR INJURY. (E.) Ruffolo, R. Dartmouth Med. Sch., Hanover, N. H.) and H. ovington. Amer. J. Path. 51(1):101-116, 1967.

aracrystalline mitochondrial inclusions were ound in electron micrographs of the livers from patients with known primary liver disease; 1, chronically-jaundiced 58-yr.-old male with ubin-Johnson syndrome and the other a 48-yr.- ld female with chronic viral hepatitis. In ddition, similar inclusions were found in ecrospy material from 3 patients without pri- ary liver disease but who showed histological vidence of liver injury. They were absent at ecropsy in 2 patients in whom no evidence of istopathologic change could be found. Post- ortem fixation of the liver in glutaraldehyde ollowed by secondary fixation in osmium tetroxide as adequate to allow evaluation of cell ultra- tructure up to 4 hr. following death. The para- rystalline mitochondrial inclusion consisted of ods or filaments measuring 60-80 Å in diameter, rouped in clusters, exhibiting geometric ymmetry and may exist in the form of coiled elices. It is concluded that their presence onstitutes evidence of hepatic cellular damage.

0739 THE INFLUENCE OF THE MICROBIAL FLORA ON LIVER INJURY AND ASSOCIATED SERUM γ-GLOBULIN ELEVATION. A STUDY IN GERM-FREE RATS TREATED WITH 3'-METHYL-4-DIMETHYLAMINOAZOBENZENE. (E.) Bauer, H. (Walter Reed Army Inst. Res., Washington, D. C.), F. Paronetto, R. F. Porro, A. Einheber and H. Popper. Lab. Invest. 16(6): 847-857, 1967.

Germ-free and conventionalized rats were inj. with 3'-methyl-4-dimethylaminoazobenzene for 6 wk. to investigate the influence of the intestinal flora on the evolution of liver disease, and to determine whether the hypergammaglobulinemia which accompanies chronic liver disease reflects excess antibody formation to bacteria. The livers, spleens and axillary and hepatic lymph nodes of the animals were subjected to histologic, autoradiographic (3H-thymidine) and immunocytochemical analysis, and their sera to immunologic studies. Germfree rats showed a greater tendency towards liver injury and cirrhosis than the conventionalized animals. This difference in susceptibility to hepatic injury was paralleled by a wt. gain of the livers in 3'-methyl-4-dimethylaminoazobenzene-treated conventionalized animals, while those of the germfree rats did not enlarge, despite greater proliferative activity. In the germfree control animals, the serum γ-globulin level and the immunologic activity of lymphatic tissue were less than in the conventionalized controls, but the increase in both parameters induced by sustained liver injury was of equal degree in both types of animal and was manifested morphologically, chiefly in the spleen and in the perihepatic nodes. This suggests that the microflora was not essential for the immune response resulting from 3'-methyl-4-dimethylaminoazobenzene-induced chronic liver injury and the ensuing hypergammaglobulinemia. Nonmicrobial factors, perhaps related to hepatocyte breakdown products alone or in association with the hepatotoxic agent, may induce a direct or adjuvant-type immune response resulting in serum γ-globulin elevation.

10740 THE INFLUENCE OF TESTOSTERONE ON THE INDUCTION OF FATTY LIVER BY METHIONINE DEFICIENCY. (E.) Sidransky, H. (U. Pittsburgh Sch. Med., Pa.), E. Verney and R. F. Egan. Lab. Invest. 16(16):858-863, 1967.

Male and female Wistar and Sprague-Dawley rats were force-fed either a basal complete diet or a methionine-deficient diet; the basal diet consisted of 9.23% essential amino acids, 8.12% nonessential amino acids, 4% salt mixture, 5% vitamin-sucrose mixture, 5% corn oil, 1.5% cod-liver oil and 67.15% dextrin; the vitamin mixture contributed 100 mg choline chloride/100 g of diet. The methionine-deficient diet had methionine (0.6% DL-methionine) replaced by an equal amount of dextrin. Animals were castrated by removal of gonads (testes or ovaries) approx. 2 wk. before the experimental diet feeding was begun; after castration, the animals received either no inj. or a s.c. inj. of testosterone propionate (6 mg) every second day until the end of the experiment. Mature intact and castrated female rats, but not intact male rats, developed a marked degree of fatty liver with a periportal distribution of the lipid when force-fed a choline-containing, methionine-deficient diet for 3 days; castrated male rats were no longer protected and developed a periportal fatty liver when fed the methionine-deficient diet. Intact female rats fed the methionine-deficient diet containing 8 nonessential amino acids developed a more severe degree of fatty liver than female rats fed the methionine-deficient diet containing glutamic acid in place of the other nonessential amino acids. Testosterone propionate admin. to castrated female or castrated male rats fed the methionine-deficient diet protected against the marked increase in liver lipid. The results indicated that testosterone in the male is most probably responsible for the protective effect in male rats against fatty liver due to a methionine-deficient diet.

10741 HEPATIC CHANGES PRODUCED BY A SINGLE DOSE OF ENDOTOXIN IN THE MOUSE. LIGHT MICROSCOPY AND HISTOCHEMISTRY. (E.) Levy, E. (Johns Hopkins U. Sch. Med., Baltimore, Md.) and B. H. Ruebner. Amer. J. Path. 51(2):269-285, 1967.

The liver lesions produced in pathogen-free mice by a single sublethal i.v. or i.p. inj. of endotoxin were studied during a 24-hr. period by light microscopy and histochemistry. The endotoxin used was Difco Bacto lipopolysaccharide *Escherichia coli* 0111:B4. I.v. inj. were given into the tail vein of 44 mice; control animals were given 0.1 ml of sterile pyrogen-free water. Experimental mice were divided into 2 groups: those of the first group received 100 µg of endotoxin, and those in the second, 300 µg. In addition, 32 were given endotoxin i.p.; 10 received 500 µg and 22 received 700 µg. Animals were sacrificed at 30 min., 1 hr., 4 hr. and 24 hr. after endotoxin inj. Qualitatively, lesions produced by i.p. inj. of endotoxin were similar to those seen after i.v. inj.; different dose levels also resulted in no essential differences. The 30-min. specimens, especially after i.p. inj., showed the mildest changes; despite variations at each time interval, a general progression of the lesions with time was discernible. Early changes included appearance of polymorphonuclear WBC in the sinusoids, swelling of Küpffer cells and platelet thrombi; later, there was aggregation of WBC and fibrin around Küpffer cells, with some apparent necrosis. Congestion and an inflammatory infiltrate were noted in the large veins. Well-marked and rapidly developing metabolic disturbances were suggested by glycogen depletion, fatty change and alterations in the localization and intensity of acid and alkaline phosphatase. The possible relationship of these changes to the mode and site of action of endotoxin and its distribution is discussed and compared with the results recorded in the literature by other methods.

10742 EFFECT OF PREDNISOLONE TREATMENT OF PREGNANT RATS ON FETAL LIVER STRUCTURE AND METABOLISM. (E.) Hill, R. B., Jr. (U. Colorado, Denver) and W. R. Blackburn. Lab. Invest. 17(2):146-154, 1967.

Pregnant Sherman-strain rats were treated with 5 mg of prednisolone daily during the final 15 days of pregnancy. Plasma free fatty acids of the dams were appreciably elevated; fetal livers contained no consistent increase in lipid glycerides, but an increase in osmiophilic droplets was regularly observed with both light and electron microscopy. Body wt. and liver wt. decreased in fetuses from steroid-treated animals. Ultrastructural alterations in the fetal liver cells included abnormal mitochondria shapes and alterations in the cristal membranes, an increase in large osmiophilic droplets, and a pattern of very intimate endoplasmic reticulum-mitochondrial relationship. There were slight increases in hepatic protein and water content in steroid-treated rat fetuses; the increase in protein content paralleled that observed in adul animals, but the water content of the dams' livers was unaffected by steroids.

10743 THE STUDY OF FREE FATTY ACID DYNAMICS IN THE PERFUSED ISOLATED LIVER FOLLOWING CCl_4 INTOXICATION. (Rum.) Costiner, E. (Endocr. Inst., Bucharest), L. Vaisler and E. Dinulescu. Stud. Cercet. Endocr. 18(2): 151-157, 1967.

When rats (260-300 g body wt.) were given CCl_4 for 12 hr., the conc. of free fatty acids in the perfusion medium of the isolated rat liver was practically unchanged for the duration of the experiment (180 min.), while free fatty acids in the perfusion medium of livers from rats with chronic (30 days) CCl_4 intoxication, decreased for the first 90 min. and then increased slightly. The free fatty acid pattern for animals with CCl_4-induced cirrhosis was similar with that of animals subjected to acute intoxication. In controls, the conc. of free fatty acids in the perfusion medium of the isolated rat liver started to increase gradually after 1 hr. The addition of free fatty acids to the perfusion medium of the isolated liver from treated (CCl_4) and untreated animals produced rapid decrease of free fatty acid values during the first hr. after which the decrease became gradually slower. The results explain certain aspects of liver fatty degeneration caused by intoxication with CCl_4 by revealing that the alterations of the liver function noticed during the first few hr. following admin. of the agent remain unchanged with time.

10784 FORMATION OF ANOMALOUS ANTIGENS IN THE EARLY STAGE OF CARCINOGENESIS IN THE RAT LIVER. (Rus.) Korosteleva, T. A. (Petrov Res. Inst. Oncol., Leningrad, USSR) and L. L. Khundanova. Vop. Onkol. 13(5):85-87, 1967.

10785 ULTRASTRUCTURAL CHANGES PRODUCED BY TRIPARANOL IN MORRIS 5123 AND NOVIKOFF HEPATOMAS. (E.) Rubright, W. C. (U. Chicago, Ill.), O. Keller and Z. Hruban. Cancer Res. 27(1):165-171, 1967.

10786 THE SALICYLATE TEST IN POSTVIRAL CHRONIC HEPATITIS. (Rum.) Zalaru, M. C. (Students Polyclinic, Bucharest). Med. Intern. (Bucur.) 19(1):59-66, 1967.

Urinary salicylate excretion was determined every hr. for 3 hr. in 70 patients (19-32 yr. old) with chronic hepatitis and in 12 controls, following p.o. admin. of 1 g sodium salicylate and 1 g sodium bicarbonate in 500 ml water. In 48 cases of stabilized postviral hepatitis, urinary salicylate excretion was significantly higher than normal in urine collected in the first and third hr., while in 19 cases with active postviral hepatitis the urinary excretion during the second and third hr. was practically normal, while during the first hr. it was slightly but significantly increased. In 3 cases with chronic cholangiohepatitis urinary salicylate excretion was similar with that in postviral hepatitis. There were no pH differences between 15 selected patients and controls following admin. of salicylate, which demonstrates that the excess salicylate found in the urine of these patients was not due to pH variations. Since urinary salicylate excretion was higher in the stabilized (regressive) form of postviral hepatitis than in the active form, the salicylate test may be used for determining the stage of the disease. The presence of regenerating liver tissue may explain the differences in urinary salicylate excretion between these 2 forms of postviral hepatitis.

10787 POTENTIAL SERUM ALDOLASE ACTIVITY, A NEW CHARACTERISTIC OF EPIDEMIC HEPATITIS. (Rum.) Anghel, A. S. (Dr. V. Babes Hosp., Bucharest). Stud. Cercet. Inframicrobiol. 17(4): 275-278, 1966.

Undiluted serum aldolase activity in 109 patients with icterogenic viral hepatitis was 85-120 U (104 U av.) while diluted (1:5) serum aldolase activity in the same patients varied between 145 and 490 U (275 U av.); in 1 case of nonicteric viral hepatitis the resp. figures were 120 and 500 U. This activity is measurable only in diluted serum, and its variations, from case to case, are significantly wider than the kinetic activity of the undiluted serum. The comparative determination of aldolase activity in diluted and undiluted serum suggests new possibilities for the diagnosis, prognosis and differential diagnosis of epidemic hepatitis.

10788 PERCENTAGE OF CASES WITH PARENTERAL MECHANISM OF INFECTION IN TOTAL EPIDEMIC HEPATITIS INCIDENCE. (Rus.) Khomiakov, A. I. (District Sanit.-Epidemiol. Station, Riazan Reg. USSR). Zh. Mikrobiol. 44(7):28-31, 1967.

Vaccination index for the district, urban, and rural regions in 1959-1964 varied between 0.6-1.5, 0.7-2.0 and 0.4-1.3, resp., and the morbidity index/10,000 population between 0.7-1 0.8-2.3 and 0.7-1.6, resp. Therefore, there wa no direct relation between the increase in vira hepatitis morbidity and vaccinations. Parenter mechanism of transmission of hepatitis was foun in 54 of 747 patients with hepatitis (being 7.2 of total morbidity of viral hepatitis), of whom 19 were in urban and 35 in rural areas. Yr. av morbidity of hepatitis for the district was 14.6, 18 for urban and 13.2 for rural districts 10,000 population; while yr. av. intensity index of morbidity of parenteral hepatitis for th district was 1.1/10,000 population (for urban 1.3 and 1.0 for rural). Fecal-oral infection was found in 519 patients, while in 174 the mechanism of infection remained unknown. Viral hepatitis morbidity intensity index was for children (up to 14 yr. old) 27.4 and for adults 9.1/10,000 population; the resp. values for intensity index of morbidity of parenteral hepati were 1.6 and 0.9/10,000 population with an av. district index of 1.1. In children under 1 an adults over 60 morbidity of parenteral hepatit was absent, though the morbidity for these age groups was 59 and 51.3/10,000 population, resp. Rise in morbidity was evident from September-January (6.7%-14.1%, being the highest in December), followed by a decrease from March-August (6.1%-4.3%); seasonal index was 1.4. Therefore parenteral mechanism of transmission hepatitis is not the leading one in the total morbidity of epidemic hepatitis.

10789 THE VARIATIONS OF MICROELEMENT GALLI IN PATIENTS WITH EPIDEMIC HEPATITIS. (Rum.) Belozerov, E. S. (Med. Inst., Sverdlov USSR). Stud. Cercet. Inframicrobiol. 17(4): 279-284, 1966.

Colorimetric determination of Ga in 217 patien (106 men and 111 women, 19-40 yr. old) with various forms of hepatitis revealed an increas of the element in the blood of all patients wi stabilized disease, regardless of severity; ho ever, the increase was greater in 62 patients with severe forms of hepatitis. Blood Ga conc increased during regression of the disease and in patients with severe and 66 cases with mild hepatitis, it became normal during clinical remission. Urinary Ga excretion, which was no mal in patients with stabilized disease, increased significantly during regression of hepatitis and returned to normal only in cases with mild forms of the disease. In patients with stabilized and regressing disease of mild and medium severity (89 cases), fecal Ga elimination was decreased but became normal du ing clinical remission, while in patients with severe disease, fecal Ga excretion remained be low normal levels. The results suggest that t variations of Ga in the blood, urine, and fece of patients with hepatitis are related to the severity of the disease.

0 BILIRUBIN FRACTION IN THE COURSE OF
EPIDEMIC HEPATITIS. (Cz.) Duliček, K.
rles U., Hradec Kralove, Czechoslovakia),
lodr and M. Horák. Cas. Lek. Cesk. 106(15):
400, 1967.

levels of free bilirubin, bilirubin mono-
uronide, and bilirubin diglucuronide in the
d of 20 patients with the jaundice type of vi-
hepatitis were followed for 5 wk. The blood
les were collected weekly, analyzed by the
od of Eberlein, and the results expressed in
total bilirubin. During the first wk. of
titis bilirubin diglucuronide represented
± 6.6% of total bilirubin. Its proportion
eased further in the course of the disease,
hing a max. (64.0±16.1) in the fifth wk.
proportion of bilirubin monoglucuronide de-
sed during the same time from 19.7±15.5 to
±9.4%. The av. levels of free bilirubin were
er (17.1-27.8%) than those of bilirubin mono-
uronide during the entire observation period.

1 THE COURSE AND OUTCOME OF FORMES
FRUSTES AND ANICTERIC FORMS OF EPIDEMIC
TITIS IN CHILDREN. (Rus.) Tret'iakova,
. (2nd Moscow Med. Inst.). Vop. Okhr.
rin. Dets. 12(5):18-22, 1967.

31 children, 80 had formes frustes and 151
teric form of viral hepatitis, 100 with a
al mild form were used for controls. Age
ed from 1-14 yr. with 59.7% being 2-5 yr.
Clinical manifestations of forme frustes of
tious hepatitis are similar to those in
al forms. However, in the majority of the
nts they were expressed very slightly. In
cases the formes frustes and anicteric forms
ral hepatitis could pass without disturbance
e general patient condition and without
ctive complaints. Basic symptoms in such
are hepatomegaly, and sometimes splenomegaly,
lso biochemical blood shifts. The distinc-
characteristic of formes frustes and an-
ic forms of viral hepatitis in children is
uick disappearance of clinical manifestations
ssary at diagnosis). However, in a number
ses even at release (30-35 days) some re-
l symptoms could be present (hepato- and
omegaly, slight biochemical shifts).
cal observation of 116 children during 3
suffering formes frustes and anicteric
of the disease, showed that the residual
oms persisted in most patients up to 3-6 mo.;
me hepatomegaly was also preserved for a
r time. This indicates a need for a dis-
ry service for children enduring formes
es of the disease. Recurrences of formes
es and anicteric forms were found in 1.6-1.8%
ses and in typical forms in 3.3% of the
. A chronic course and formation of liver
osis was not observed in children enduring
s frustes and anicteric forms of this
se.

10792 DETECTION OF ANICTERIC FORMS OF EPIDEMIC HEPATITIS IN PEDIATRIC INSTITUTIONS OF NOGINSK. (Rus.) Khramova, L. P. (Noginsk City Hosp., USSR). Zh. Mikrobiol. 44(7):31-34, 1967.

In 1965 viral hepatitis, in 45% of those with hepatitis, developed for the first time actively; in 50.5% it was diagnosed as anicteric and formes frustes of the disease. The results of prophylactic measures among children used in foci of viral hepatitis (day nursery, kindergarten, school) showed that of 8710 children examined 91 (1.4%) were ill; 440 examined for aldolase and transaminase activity in the blood 85 (18%) were ill; of 8616 examined for presence of bile pigments in the urine 25 (0.3%) were ill; of 177 with grippe and catarrh of the upper respiratory tract 15 (8.4%) were ill; of 77 hospitalized in the diagnostic ward 51 (66.2%) were ill. Therefore, hospitalization of contacted persons with increased enzyme activity and appearance of catarrhal symptoms is necessary. Frequency of development of anicteric, formes frustes or jaundice form of epidemic hepatitis was in 1964, 1%, 9%, or 90%, resp., in 1965, 16%, 34%, or 50%, resp. Massive outbreaks in childrens institutions had some general patterns; they appeared if the first patient had pronounced catarrhal symptoms and prolonged (up to 2-3 wk.) prodromal period, a significant part of which elapsed in the institution; subsequent cases appeared as an outbreak of up to 5-6 cases and later as a chain lasting up to 1 mo. (incubation period 7-22 days); clinically the disease had anicteric and formes frustes in 50% of the cases. In all the children institutionalized up to fourth grade γ-globulin was used in the dose of 1.5 and 1.0 ml. Of 2573 contracted persons vaccinated by γ-globulin 117 (4.6%) became ill, while among nonvaccinated the resp. value was 99 of 1116 (8.9%). The poor effectiveness of γ-globulin is due to late vaccination (later than 5 days after contact) in 88% of the cases.

10793 CHANGES IN THE BLOOD SERUM LEVEL OF FREE AMINO ACIDS IN CHILDREN SUFFERING FROM EPIDEMIC HEPATITIS. (Rus.) Spektor, E. B. (Moscow Sci. Res. Inst. Child. Surg.). Vop. Okhr. Materin. Dets. 12(5):26-31, 1967.

Study of 16 patients with mild form (Group 1), 16 with moderately-severe form (Group 2) and 5 with severe form (Group 3) of infectious hepatitis showed changes in blood serum amino acid level in all; they were most pronounced in Group 3 as compared to 10 healthy children. Total amount of amino acids in Group 3 was increased in all patients; a significant increase was found in conc. of threonine, glutamic and aspartic acids, tyrosine, methionine, alanine, glycine and phenylalanine; a lower increase in conc. of glutamine and serine; a decrease in conc. of valine and leucine;

while the conc. of lysine, histidine, arginine, cystine and tryptophan were increased or decreased. In Group 2 an increase of glutamic acid was found in 10; threonine, aspartic acid, glycine, serine and phenylalanine content in 6; methionine content in 8; while the content of lysine, leucine and valine was somewhat decreased in 14. In Group 1 an increase, which was less pronounced than in Group 2, in the level of glutamic and aspartic acids, serine and glycine was found in 7, and that of methionine, threonine, and phenylalanine in only 2, while the lysine, valine, and leucine content were decreased. In Group 1 (6 patients) and Group 2 (4 patients) and in patients in the climax of the disease, the total amount of amino acids was significantly decreased due to a sharp decrease of conc. of serine, aspartic acid, histidine, arginine, threonine, alanine, glycine, lysine, valine, and leucine. In the majority of cases in Group 1-2 in the period of regression of symptoms and reconvalescence, faster positive dynamics were noted than in Group 3; however a complete normalization of amino acid composition was found at clinical cure in only 3 patients. In the remaining patients the composition was disturbed due to a conc. change of 2-3 amino acids, e.g., increase in conc. of alanine, glycine, serine, and aspartic acid, or decrease in conc. of lysine, valine and leucine. Almost all these patients showed residual symptoms of epidemic hepatitis (splenomegaly, increased bilirubin, and others). Results studied in 20 children showed a normalization of amino acid composition in 25% of the children; after 1 yr. half had an amino acid level not yet completely restored. Changes in free amino acid content in infectious hepatitis directly depends on the form and period of disease. The most pronounced shifts were found in patients with severe form at the climax of the disease; a certain parallelism was noted between the degree of the disturbance of the amino acid level and the degree of dysproteinemia; however, a complete correlation with clinical manifestations of disease, with bilirubin level and with serum enzyme activity was not found. A necessity for a carefully differentiated approach to an incorporation of protein hydrolyzates, amino acid mixtures, and single amino acids in the complex of therapeutic measures in infectious hepatitis is stressed. In all the periods of disease chromatographic analysis of amino acids in the blood could serve as an additional test for hepatic function.

10794 BEHAVIOR OF CEREBROSPINAL TRANSAMINASES IN THE COURSE OF NEUROLOGICAL FORMS OF VIRAL HEPATITIS IN INFANCY. (It.) Laterza, G. (Child. Hosp., Bari, Italy) and D. De Serio. Minerva Pediat. 19(19):949-951, 1967.

Transaminase activity was determined in the cerebrospinal fluid of 10 children (8 male and 2 female; age 1.5-13 yr.) with severe neurological manifestations in the course of viral hepatitis. In 7, the neurological symptoms (convulsions,
delirium, sleepiness, tremor, and others) were
present at the onset of the disease, while in
the other 3, they appeared during the final
stage of acute yellow atrophy. Transaminase
levels were determined according to the
Friedman-Haugen colorimetric method (modified)
in 0.2 ml samples of cerebrospinal fluid carefully obtained so as to exclude the presence o
blood. Other routine laboratory tests were als
conducted. Cerebrospinal levels of glutamic-oxalacetic and glutamic-pyruvic transaminase we
within normal limits (12-25 U and 6-18 U, resp
in 7 patients but markedly increased (60-125 U
and 48-65 U, resp.) in the other 3. On the ot
hand, SGOT and SGPT levels were greatly increased (220-900 U and 300-1000 U, resp.) in a
patients. No correlation was seen between ser
and cerebrospinal transaminase levels; in 2 of
patients with high cerebrospinal levels, serum
levels were even lower than those observed in
patients with normal cerebrospinal levels. Th
3 patients with high cerebrospinal levels show
signs of hemorrhagic diathesis and had patholo
gical hemocoagulation (Quick, prothrombin, Fac
VII, proaccelerin) tests; all 3 died from
hemorrhage. Results indicate that the transaminases present in the cerebrospinal fluid
originate endogenously from the CNS. In
patients with high cerebrospinal levels, neuro
logical symptoms may be considered secondary t
hemorrhagic lesions, whereas in patients with
normal cerebrospinal levels, neurological symp
toms are of an infectious nature or a result c
metabolic disturbances due to hepatic insufficiency.

10795 TREATMENT OF JUVENILE HEPATITIS BY PREDNISONE. (Cz.) Morávková, J. (Thomayer Hosp., Prague-Krc). Cesk. Pediat. 21(10):876-879, 1966.

Treatment by prednisone of children with infe
tious hepatitis is indicated in the following
cases; symptoms indicating that the CNS has b
affected, symptoms of chronic hepatitis or
cirrhosis, prolonged cholestasis, and prolong
aversion towards food with symptoms of depres
In 1962 13 of 683 were treated with predniso
(av. 423 mg during 23 days). The initial dai
dose was 40 mg admin. in 4 portions which was
then gradually decreased. After 3-9 days bil
rubin disappeared from the urine. The levels
of Na and K became normal and the number of W
was less than 10,000 after the end of treatme
Among the children treated with Prednisone on
1 relapse was observed. In 1963, 21 of 967
hospitalized children were treated with
Prednisone. The initial daily dose was reduc
to 20-30 mg (0.5 mg/kg wt.). Each receiving
av. 292 mg during the 18 days. Their conditi
improved rapidly and relapses were not observ
during this yr.

10796 EFFECTS OF PREDNISONE TREATMENT DUR
THE ACUTE PHASE OF VIRAL HEPATITIS

HE INCIDENCE OF POST-HEPATITIS LIVER DISEASES AT -3 YEARS AFTER THE DISEASE. (STATISTICAL VALUATION OF 187 CASES). (It.) Da Villa, G. U. Naples, Italy), F. Fiorentino and F. Piccinino. . *Mal. Infett.* 18(12):835-840, 1966.

mong 187 patients (110 male and 77 female; 4.75% between 2-14 yr. old and 65.25% between 4-60 yr. old) selected 1-3 yr. after an acute pisode of viral hepatitis, 80 had been treated ith prednisone (0.5 mg/kg/day p.o.) for 10 days nd 107 (controls) had been given routine treat- ent (liver extracts, vitamins). Patients were elected for study on the basis of their having een hospitalized within 10 days of the appear- nce of jaundice and their being followed up to ne time of cure. Patients were considered to ave post-hepatitis liver disease if 1-3 yr. fter an acute episode of viral hepatitis they nowed positive response to 3 of 6 routine liver unction tests with or without concomitant linical signs. The overall incidence of post- epatitis liver disease in all patients was).75%. The incidence of post-hepatitis liver isease was higher (23.4%) among patients not reated with prednisone than among those treated ith prednisone (13.7%). No significant differ- nce was observed between the incidence of post- epatitis liver disease in the 2-14 (30.3%) or 4-60 yr. old (20.3%) groups. No significant ifference was observed in the incidence of liver athology among males or females in the group ot treated with prednisone, while the prednisone- reated group showed a higher incidence of liver athology among males (18.9%) than among females 3.7%). No significant difference was noted in ne incidence of liver disease among patients reated with prednisone for short (10-20 days) or ong (20-40 days) periods, nor in those treated n the early (within 10 days after the appearance f jaundice) or late (more than 10 days after the ppearance of jaundice) phase of viral hepatitis.

)797 ACTUAL AND DISPUTABLE PROBLEMS OF CORTICOSTEROID THERAPY OF BOTKIN'S ISEASE. (Rus.) Geller, L. I. (Khabarovsk Med. nst., USSR), Z. P. Kozlova and T. P. Glinskaia. *rach. Delo* (4):112-113, 1967.

study was made on 130 persons who had viral epatitis (moderately-severe to severe forms) .5-4.0 yr. before observation (80 of the atients received prednisolone, usually a total f 250-300 mg in 2 wk.), and on 23 patients who ad the severe form of viral hepatitis during ne preceding yr. and received no corticosteroid nerapy. In patients with the severe form, nronic hepatitis developed somewhat more fre- uently than in patients with a moderately-severe orm. At the same level of severity of viral epatitis, the frequency of transition to chronic epatitis was similar in both prednisolone- reated and untreated patients; the difference as statistically insignificant. Also among nese 2 groups, there was no essential difference n the frequency of inflammatory processes in the bile tract in the remote period after viral hepatitis. In patients with viral hepatitis, the following were noted: a reduced partial acidity of the gastric juice, a tendency toward a hypokinetic form of the electrogastrogramm as an indicator of reduced motor function of the stomach, RBC macrocytosis, thrombocytopenia, decreased osmotic stability of WBC, and in some, a decrease of the functional reserves of the adrenal cortex as determined by excretion of 17-hydroxycorticosteroids in response to loading with ACTH. The frequency of all of these disturbances in patients enduring viral hepatitis was similar for both prednisolone-treated and untreated patients. Thus, corticosteroid therapy in viral hepatitis does not prevent the development of chronic hepatitis, and a number of functional disturbances of the stomach, adrenal cortex and blood parameters, at the same time, do not promote development of these pathologic changes in the remote period after viral hepatitis.

10798 HARMLESSNESS OF γ-GLOBULIN, PREPARED FROM SERUM MIXTURE, INCLUDING THE SERUM OF AN EPIDEMIC HEPATITIS PATIENT (ACCORDING TO THE DATA OF AN EPIDEMIOLOGICAL TRIAL). (Rus.) Stepanov, G. P. (Moscow Inst. Epidemiol. & Mikrobiol.), T. M. Khrometskaia, V. A. Kamenskii, T. P. Zinina, A. G. Balashova, E. S. Narolina, E. F. Kireeva and M. A. Vaistikh. *Zh. Mikrobiol.* 44(7):34-40, 1967.

In Voronezh in 1964-5, 5712 children (age 1-8 yr., Group 1) were vaccinated by experimental (hepatitic) and 5861 (age 1-8 yr.; Group 2) by control (normal) series of γ-globulin. The morbidity in Group 1 was 13 of 5712 (2.28%) or 2.28/1000 children and in Group 2, 17 of 5861 (2.90%) or 2.90/1000 children during a 1-yr. period. In both groups the morbidity was equal at the same period. Morbidity indices in Group 1 did not depend on the time of maintenance of γ-globulin nor on the degree of possible infectivity of the original mixture of sera. During the first 7 mo. of observation (June-December) morbidity among the children of both groups was the same. In Group 1 during the first 4 mo. of observation (optimal incubation period in serum hepatitis) not 1 child had hepatitis. The series of γ-globulins prepared from the mixture of sera from epidemic hepatitis patients proved to be harmless.

10799 REMOTE RESULTS OF MASS GAMMA-GLOBULIN VACCINATION AS A METHOD OF EPIDEMIC HEPATITIS PROPHYLAXIS. (Rus.) Spotarenko, S. S. (Cent. Inst. Epidem., Moscow). *Zh. Mikrobiol.* 44(4):58-62, 1967.

Randomly-selected kindergarten and school children from 342 children's institutions were divided into 3 groups; Group 1 (30,038 children) were mass inoc. with γ-globulin (1.5 ml); Group 2 (22,609) were inoc. with 3 ml following signs of epidemic; Group 3 (20,413) were used as controls. Mass prophylaxis of epidemic hepatitis by γ-globulin in the pre-epidemic period in the first yr. of observation was 1.9 times more effective than inoc. after appearance of the epidemic. In the second yr. the morbidity level in the group with earlier mass inoc. was 1.3 times higher than in the group inoc. after epidemic appearance. Morbidity/1000 children in 1963-1964 was as follows: Group 1 - 5, Group 2 9.6 and for Group 3, 14.5; in 1964-1965 it was, resp., 12.5, 9.6 and 12. The morbidity (according to mo.) was approx. the same in all groups. The number of cases (%) and focal coefficient were, in the first yr. as follows: Group 1, 5.5 and 2.44, resp., in Group 2, 64.9 and 2.86, resp., in Group 3, 62.7 and 4.6, resp. In the second yr. in Group 1 it was 74.7 and 4.3, resp., in Group 2, 69.1 and 3.1, resp., in Group 3, 73.5 and 3.8, resp.

10800 CYTOMEGALOVIRUS HEPATITIS IN THE ADULT. (E.) Toghill, P. J. (King's Coll. Hosp., London), M. E. Baily, R. Williams, R. Zeegen and R. Bown. Lancet 1(7504):1351-1354, 1967.

In 2 patients a cholestatic hepatitis was associated with high and protracted fever, atypical mononuclear cells in the blood, episodes of hemolysis and negative Paul-Bunnell reactions. In a 56-yr.-old man with acute myocardial infarction, at the peak of jaundice, serum-bilirubin increased to a peak of 10 mg/100 ml, SGOT to 480 U/ml (normal range, 5-30), alkaline phosphatase to 42 King-Armstrong U/ml, and serum-albumin decreased to 2.4 g/100 ml. This patient was treated with i.v. heparin and phenindione. Liver biopsy revealed features of an acute hepatitis, indistinguishable from viral or drug origin, and moderate cholestasis. Complement-fixing antibody titer for cytomegalovirus was 128 on both of 2 occasions; cytomegalovirus was isolated from the urine. In a 23-yr. old woman treated by open-heart surgery for closure of a ventricular septal defect, mild anorexia and a temperature spike to 104°F was accompanied by jaundice, serum total bilirubin of 16.4 mg/100 ml, SGOT of more than 400 U/ml (normal, 15-40), alkaline phosphatase of 81 King-Armstrong U and serum-B_{12} conc. of 730 pg/ml. Liver biopsy disclosed slight cholestasis and a picture of subacute hepatitis with fibrosis. Soon after onset of illness, cytomegalovirus complement-fixing antibody titer was less than 8, but 35 days later it had risen to 512; it was isolated from urine 48 days after start of the illness. It is suggested that in each of these 2 cases, cytomegalovirus infection was the cause of hepatitis, and that infection with cytomegalovirus may be a commoner cause of hepatitis than has previously been thought.

10801 ELECTRON MICROSCOPY OF THE HEPATOCELLULAR AND KUPFFER-CELL LESIONS OF MOUSE HEPATITIS, WITH PARTICULAR REFERENCE TO THE EFFECT OF CORTISONE. (E.) Ruebner, B. H. (Johns Hopkins U. Sch. Med., Baltimore, Md.), T. Hirano and R. J. Slusser. Amer. J. Path. 51(2):163-189, 1967.

Female pathogen-free CD I weanling mice received 0.1 ml of a virus suspension of the MHV_3 strain of mouse hepatitis; cortisone acetate was inj. s.c. once/day at a dose of 2.5 mg/animal. Cortisone not only increased the number and size of the necrotic foci produced by MHV_3 virus but also altered the histologic appearance of the necrotic parenchymal cells when observed under light microscopy. Instead of becoming uniformly hyalinized, hepatocytes became markedly swollen and subsequently underwent a lytic type of necrosis. Cytoplasmic virus formation was seen most clearly in hepatocytes of cortisone-treated mice. Particles appeared to form in relation to newly synthesized cytoplasmic aggregations of ribosome-like particles and acquired an outer envelope by budding through smooth membranes that were probably derived from proliferated endoplasmic reticulum. Hyalinization seemed to correspond to 2 ultrastructural lesions. One of these was the development in hepatocytes of dense, often focal, cytoplasmic degradation with loss of ribosomes and membrane proliferation. Less commonly there was proliferation of smooth endoplasmic reticulum. Both of these alterations were occasionally observed in Kupffer cells. Lytic necrosis in hepatocytes of cortisone-treated animals corresponded to marked intracellular edema, striking mitochondrial swelling with calcification of the cristae, and the formation of intracellular vacuoles possibly derived from focally dilated endoplasmic reticulum or pale cytolysomes. Irrespective of cortisone admin., necrosis in the Kupffer cell was usually of the lytic variety.

10802 EXPERIMENTAL VIRAL HEPATITIS IN THE DOG: PRODUCTION OF PERSISTENT DISEASE IN PARTIALLY IMMUNE ANIMALS. (E.) Gocke, D. J. (Columbia U. Coll. Physicians & Surgeons, New York, N. Y.), R. Preisig, T. Q. Morris, D. G. McKay and S. E. Bradley. J. Clin. Invest. 46(9):1506-1517, 1967.

Experimental infection with canine hepatitis virus was studied in 49 dogs. The pattern of response to infection was distinctly modified by the immune status of the animal; all of 19 fully susceptible dogs had an acute, fulminating fatal hepatitis when infected with a standard dose of virus, and all of 19 dogs with high levels of immunity to the virus survived without apparent illness. Eleven dogs were spontaneousl encountered with partial immunity to the infectious agent; these animals developed different, prolonged forms of hepatitis after infection. In 4 animals death occurred in 8-21 days after what was termed a subacute course; the remaining 7 dogs survived up to 8 mo. with evidence of chronic liver damage. The chronic and subacute forms of hepatitis were reproduced

perimentally in 7 of 8 fully susceptible dogs
at were passively immunized against the canine
patitis virus by admin. of hyperimmune serum.
though the virus could be found in sites of
patic damage in the early stages of the sub-
ute and chronic diseases, it could not be
monstrated in the later stages which were
aracterized by persistent liver damage and a
rked chronic inflammatory reaction. Dogs with
ronic hepatitis eventually developed extensive
patic fibrosis.

803 INDUCTION OF TUMOURS IN HAMSTERS WITH
INFECTIOUS CANINE HEPATITIS VIRUS.
.) Sarma, P. S. (Microbiol. Assoc., Bethesda,
.), W. Vass, R. J. Huebner, H. Igel, W. T. Lane
d H. C. Turner. Nature (London) 215(5098):
3-294, 1967.

derle Strain 255 of infectious canine hepatitis
s used in these studies. A virus preparation
issue culture inhibitory dose$_{50}$, titer 107/ml)
s made by a single passage in canine kidney
lls and inoculated into 14 (3 litters) newborn
msters; each hamster was inoculated with 0.1
/site by i.p. and s.c. routes. Two of the 14
oculated hamsters developed 10-20 mm tumors at
e site of inoculation, the first appearing on
y 360 as a s.c. tumor and the second as an i.p.
mor on day 403. When they had reached a size
30 mm, the tumors were surgically removed,
nced to small pieces and transplanted s.c. into
wborn as well as weanling hamsters, most of
ich developed tumors. The serial s.c. trans-
ants of the i.p. tumor grew rapidly in newborn
msters and reached sizes of 40-60 mm within
6 wk.; growth of transplants in weanling ham-
ers was less rapid and some of the inoculated
msters failed to develop tumors. The primary
ral-induced s.c. tumor was a low-grade fibro-
rcoma that manifested its morphological
aracteristics on transplantation in hamsters;
e primary i.p. tumor was an undifferentiated
oplasm. Hamsters developing large transplanted
p. line tumors which survived beyond the fifth
. usually developed complement-fixing serum
tibodies that reacted with the homologous tumor
tigen and with T antigens of strain 255 and
eybridge' strain of infectious canine hepatitis
rus prepared from infected canine kidney and
rret lung cultures. Such complement-fixing
tigens and antibodies were not detected in
msters bearing the primary tumor or secondary
ansplants of the primary s.c. tumor. The
activity of the antigen and antibody described
peared to be specific for infectious canine
patitis hamster tumor system and infectious-
nine-hepatitis-virus-infected cultures.

827 PERITONEAL ATRIAL SHUNT FOR INTRACTABLE ASCITES. (E.) Hyde, G. L. (U. Ken-
ucky Coll. Med., Lexington) and B. Eiseman.
ch. Surg. (Chicago) 95(3):369-373, 1967.

implantable device consisting of an intra-
eritoneal sump, 1-way valves, a manually com-
ressible Holter pump and indwelling i.v. tubing
eading into the right atrium was used in 8
atients (49-77 yr. old; 7 with nutritional
irrhosis and 1 with postnecrotic cirrhosis; 1
lso had hepatocellular carcinoma) for relief of
ntractable ascites. Severity of the liver
isease was reflected by serum albumin conc. of
ess than 2.5 mg/100 ml in all patients; 5 were
linically jaundiced and all but 1 had a blood
rea N conc. of more than 30 mg/100 ml. One
atient is alive and ascites-free at the time of
eport with a functioning shunt 2.5 yr. after
peration; 4 died of liver disease 2-5 mo.
stoperatively; 1 died in heart failure with no
vidence of congestive failure in the immediate
ost-shunt period. Two patients died of com-
lications of the shunt operation; in every
atient, the shunt was patent at the time of
eath. On 4 occasions in 2 patients it was
ecessary to reoperate to clear the system of
ccluding fibrin clots. Although the device is
ot totally perfected, it is concluded that it is
worthwhile mechanical adjunct for the control
f ascites.

828 EMERGENCY PORTACAVAL SHUNT: A COMPARATIVE STUDY OF SHUNT, VARIX LIGATION AND
NSURGICAL TREATMENT OF BLEEDING ESOPHAGEAL
ARICES IN UNSELECTED PATIENTS WITH CIRRHOSIS.
E.) Orloff, M. J. (Harbor Gen. Hosp., Torrance,
alif.). Ann. Surg. 166(3):456-478, 1967.

prospective study of emergency treatment of
leeding esophageal varices in unselected patients
ith cirrhosis was conducted; 40 unselected,
dult patients (28 men, 12 women; 38 Caucasians,
Negroes; 33-65 yr. old, with a mean age of 49
r.) with moderate-to-advanced alcoholic cirrhosis
nd bleeding varices were subjected to an emer-
ency portacaval shunt within 8 hr. of admission
o the hospital; 58% had clinical jaundice, 43%
ad ascites and 20% had encephalopathy at time
f admission. Almost all patients had severe
epatic dysfunction and hypokalemic alkalosis
as present in 50% of the subjects in whom blood
ases and pH were measured. I.v. posterior
ituitary extract temporarily controlled bleeding
reoperatively in 88% of the group. Every
atient had portal hypertension; 15 had an end-
o-side portacaval anastomosis and 25 had a side-
o-side shunt, both of which reduced the portal
ressure markedly and controlled the bleeding in
very case. Postoperatively, 58% developed
epatic coma, 45% had delerium tremens, 20%
eveloped a peptic ulcer and 83% had alkalosis.
wenty-one of the 40 patients recovered from
peration, an early survival rate of 53%; 75% of the postoperative deaths were due to hepatic failure. With the exception of 1 patient who was followed for slightly less than a yr., survivors were followed for from 13-50 mo; 17 were still alive at time of report and the predicted 4-yr. survival rate calculated by the life-table method was 43%. Liver function improved significantly in 73% of the survivors and most have had active and useful lives. Two-thirds of the survivors have abstained from alcohol. Analysis of potentially preoperative and operative factors showed that only the presence of unstable ascites and of hypokalemic alkalosis affected the outcome. Survival of significant numbers of patients with 1 or another of the serious manifestations of cirrhosis suggested that, except for obviously decompensated cirrhosis with concurrent jaundice, ascites and encephalopathy, there are no clear contraindications to operation. Results of emergency portacaval shunt were compared with those obtained in previous prospective studies of medical treatment and of varix ligation. In comparable patients, both forms of operative therapy produced an early survival rate which was 3 times greater than that resulting from medical management. The 4-yr. survival rate after emergency shunt was significantly greater than the survival rate with the other types of treatment. The findings of this study suggest that early and definitive operative control of varix hemorrhage provides the cirrhotic patient with the greatest chance of surviving. Although studies involving larger numbers of patients are clearly necessary, it is suggested that the emergency portacaval shunt is the therapy of choice for most cirrhotic patients who bleed from esophageal varices.

10829 PLASMA VOLUME IN CIRRHOSIS OF THE LIVER: ITS RELATION TO PORTAL HYPERTENSION, ASCITES AND RENAL FAILURE. (E.) Lieberman, F. L. (John Wesley County Hosp., Los Angeles, Calif.) and T. B. Reynolds. J. Clin. Invest. 46(8):1297-1308, 1967.

Plasma vol. was measured by using albumin-^{131}I- and ^{51}Cr-labeled RBC in 24 control subjects (16 men, 8 women), 140 patients with hepatic cirrhosis, and 10 patients (6 men, 4 women) with no cirrhosis but a variety of portal-systemic shunts for relief of portal hypertension; 63 (44 men, 19 women) had cirrhosis and no ascites, 34 (22 men, 12 women) had cirrhosis with ascites; 48 (33 men, 15 women) had cirrhosis and end-to-side or side-to-side portacaval anastomosis for relief of portal hypertension; 15 (13 men, 2 women) had cirrhosis and ascites complicated by functional renal failure. Almost all the patients with cirrhosis had a history of chronic alcoholism. Elevated values for plasma vol., by both methods, were found in each group of patients (aside from controls). The lymph space drained by the thoracic duct was measured by a radioisotopic technic in 6 patients with cirrhosis and ascites; the amount of radioactivity in this space was negligible in accounting for the elevated plasma vol. Similar results were obtained when the degree of leakage of albumin-^{131}I into the ascites was determined in 10 patients with cirrhosis. Plasma vol. was unusually elevated in patients who had bled from esophageal varices, and paired comparisons before and after portacaval shunt normal values; there was a statistically significant correlation between normal values. A statistically significant correlation was also found between plasma vol. and wedged hepatic venous pressure measured in 36 patients. It is concluded that the elevated values for plasma vol. in cirrhosis are valid and are not artifacts due to leakage of albumin-^{131}I from the circulation during mixing; it is also concluded that portal hypertension is responsible for expansion of the plasma vol. However, the authors, on this basis, were unable to explain the failure of portacaval shunting to return the plasma vol. to normal, unless the shunt or some other factor kept the plasma vol. elevated.

10830 PORTAL HYPERTENSION IN CHRONIC HEPATITIS AND LIVER CIRRHOSIS. LAPAROSCOPIC AND SPLENOPORTOGRAPHIC OBSERVATIONS. (Rus.) Loginov, A. S. (Ther. Inst., Moscow), G. S. Magnitskii and L. S. Matveeva. Ter. Arkh. 39(3): 29-37, 1967.

In 10 patients (21-57 yr. old) with chronic hepatitis, laparoscopy revealed enlarged liver, thickening of capsule, and sometimes perihepatitis; intrasplenic pressure (in mm H_2O) ranged from 100-250. Moderate dilatation of the vessels of the stomach, omentum, and parietal peritoneum was found in 3 by laparoscopy, and slight dilatation by splenoportogram of splenic and portal vein in 4. Architectonics of intrahepatic ramifications of portal vein was normal. In 24 patients (age 30-62 yr.) with postnecrotic liver cirrhosis of 6 mo-15 yr. duration showed liver deformation of various degrees. Clinicoroentgenologic signs of portal hypertension were found in only 15 patients; however, all showed increased (240-560) intrasplenic pressure. Splenoportograms showed dilatation and twisting of splenic vein, dilatation of portal vein and formation of collateral tract outflow; laparoscopy revealed dilatation and twisting of small ramifications of portal vein, and dilatation of veins of ligamentum teres hepatitis, of parietal and visceral peritoneum, of omentum, stomach and diaphragm. In many patients architectonics of the liver portal bed was changed; e.g., vascular picture was impoverished and deformed. In 6 of 24 splenoportograms, partial or complete obstruction of splenoportal stem, conditioned mostly by thrombosis was observed. In 14 patients (36-72 yr.) with portal liver cirrhosis of 1-12 yr. duration morphologic hepatic changes were characterized by micronodular type of regeneration. Intrasplenic pressure was increased (330-517); splenoportograms showed dilated splenic vein in 4 and dilated portal vein in 5; portacaval collaterals were found in 4. Laparoscopy revealed dilated and twisted veins of omentum, stomach, hepatic capsule, gallbladder, parietal and visceral peritoneum, ligamentum teres hepati and diaphragm. Architectonics of intrahepatic ramifications of portal vein was similar as in the patients with postnecrotic cirrhosis. In 7 (33-49 yr.) with primary (5) or secondary (2) biliary liver cirrhosis of 1-8 yr. duration morphological characteristics were close to thos in portal cirrhosis except it proceeds with intr hepatic cholestasis. Portal hypertension could be determined only by instrumental methods. Intrasplenic pressure was increased (230-427) in all. Some dilatation of the splenic and portal vein was found in only 1; portal vein obstructio in 1; collateral blood circulation in 4; and ascites in 1. The intrahepatic picture of porta vein ramifications had no specific characteristi

10831 THYROXINE TURNOVER AND TRANSPORT IN LAENNEC'S CIRRHOSIS OF THE LIVER. (E. Inada, M. (Bronx VA Hosp., N. Y.) and K. Sterlin J. Clin. Invest. 46(8):1275-1282, 1967.

Studies of the metabolism of thyroxine in 14 men with cirrhosis of the liver associated with alcoholism showed a variety of deviations from normal. In addition to radiothyroxine turnover studies, determinations were made of the free thyroxine fractions and free thyroxine I conc. in serum (Mg precipitation method) as well as th max. binding capacities of thyroxine-binding α-globulin and thyroxine-binding prealbumin by reverse flow paper electrophoresis in a glycine acetate system at pH 8.6. All cases of cirrhosi showed diminutions in thyroxine-binding prealbumin capacities but their thyroxine-binding α-globulin capacities showed a wide scatter (13.4-41.6 μg/100 ml). The free thyroxine fraction was quite variable, with distinct elevation in 9 of 17 sera. The binding proteins appeared to be determinants of the free thyroxine fraction, which in turn appeared to be a direct determinant of the half-time of turnover; these inferences did not exclude other possible factors, including diminished hepatic uptake and metabolism of the hormone in liver disease. In spite of considerable alterations in biological half-times, free thyroxine values and binding proteins, it was remarkable that the absolute hormone disposal was normal in all 14 patients with cirrhosis of the liver.

10832 LUPOID CIRRHOSIS WITH SERUM LACTIC ACID DEHYDROGENASE LINKED TO AN γ A IMMUNOGLOBULIN. (E.) Ganrot, P. O. (Malmo Gen. Hosp., Sweden). Experientia 23(7):593, 1967.

Under agarose gel electrophoresis, serum from a patient with lupoid cirrhosis with jaundice showed an abnormal mobility and increased width of the zones of all the isoenzyme fractions of LDH; this was interpreted as evidence of LDH-isoenzymes being bound to some serum protein

LIBRARY U. OF I. URBANA-CHAMPAIGN

th a low charge. The serum was fractionated by l filtration in a Sephadex G 200 column; distribution of the activity among the fractions sembled that of a homogenous protein fraction uted from the column somewhat before γG, whereas H is normally eluted after γG. Paper electrooresis of the serum showed a low albumin conc. .1 g/100 ml), and a massive polyclonal increase γ-globulin (2.5 g/100 ml); immunochemical alysis showed the serum conc. of γG, γA and γM be 195, 220, and 250%, resp., of normal. LDH-actions sid not migrate in specific antihuman , but did so in anti-γG and anti-γM; none of ese antisera affected the mobility of normal H-isoenzymes. Equal vol. of lupoid serum and rum from another patient with myocardial inrction were mixed; no LDH-fraction with normal bility could be demonstrated in the mixture; is showed that a considerable amount of free H-binding protein occurred in serum, and also at normal LDH could be bound. From this it was sumed that the patient's own LDH was also norl and that the abnormal LDH pattern was due to e presence of an abnormal γA fraction. The ta indicated very high specificity and strong teraction between an γA-fraction and LDH. The mplex LDH-γA was not dissociated on gel filtraon in neutral pH, and it is therefore probable at the complex occurred *in vivo* in the patient's n blood.

833 URINARY ALDOSTERONE CONTENT IN PATIENTS WITH LIVER CIRRHOSIS. (Rus.)
etagurova, A. N. (Leningrad Sanitary-Hygiene d. Inst., USSR). *Vrach. Delo* (4):18-20, 1967.

a study on 20 patients (18 males, 2 females; -54 yr. old) with liver cirrhosis of 4 mo.-23 . duration, it was found that aldosteronism veloped in the period of active progression; is was conditioned by the inability of the liver inactivate aldosterone. All of the patients re divided into 3 groups according to the stage the disease: 1) the initial stage; 2) stage formed cirrhosis; and 3) dystrophic stage dvanced); the patients were also subdivided cording to the degree of portal hypertension to 4 stages: I. determined only by instrumental thods; IIA-clinical dyspepsia, splenomegaly tages I and IIA were found in 9 patients); IIB-cites, venous collaterals, varicose dilatation the esophageal veins (found in 10); III-mpensated by surgery (found in 1 patient). The ysiological fluctuation of aldosterone in the ily urine was 1-10 μg (av. 6.8 μg). In 2 tients of the first group with portal hyper-ension I-IIA and the inactive phase aldosterone nc. was 10.3 and 12.0 μg, resp. In patients Group 2 with portal hypertension I-IIA and active phase, aldosterone excretion was 12.7 d 15.0 μg, and in the active phase in 4 tients, it varied from 20.4-44.3 μg (av. 33.3); in 5 other patients with IIB portal hyper-ension and active phase, aldosterone secretion ried from 29.9-75.0 μg (av. 50.2 μg), and in 1 tient in the inactive phase, it was 15.3 μg. In 1 patient of Group 3 with I-IIA portal hypertension and inactive phase, aldosterone content in the urine was 16.1 μg, and in 4 patients with IIB portal hypertension and active phase, it ranged from 34.3-3-72.0 μg (av. 45.3 μg). Thus, the level of aldosterone excretion depended very little on the degree of portal hypertension. Biochemical indices of liver function revealed a significant disturbance in liver function during the active phase which concurred with the increase in aldosterone excretion in the urine. In the dystrophic phase of liver cirrhosis with pronounced liver insufficiency, the excretion of aldosterone in the urine was low; this was caused by reduction of secretion of mineralocorticoids by the adrenal cortex.

10834 COMPARISON OF ORAL ISOSORBIDE AND INTRAVENOUS MANNITOL AS ADJUNCTS TO THE DIURESIS OF PATIENTS WITH CIRRHOSIS OF THE LIVER. (E.) Gagnon, O. (Duke U. Sch. Med., Durham, N. C.), P. M. Gertman and F. L. Iber. *Amer. J. Med. Sci.* 254(3):284-295, 1967.
